A. B. C. Injector Carburetor. Desc. with diagram 19
A. B. C. Motors: Illus. art. with drawing.. 526
A. E. G. Aeroplanes: Brief desc. with illus. 494
  Type C. IV (Brief note and drawing).. 776
  Dimensions and Equipment.... 780
Accessories:
  Herz Spark Plug Illus. desc.... 21
  Stewart Duplex Carburetor (Illus. desc.) 21
  Worcester Pressed Steel Parts (Illus. desc.) 21
  Ideal Radiators (Illus. desc.).... 21
  Fafnir Ball Bearings (Illus. desc.).... 21
  Bigelow Spark Intensifier (Illus. desc.). 21
Accidents:
  Privates Ransome H. Merritt and Anthony P. Spilener Killed at Mineola.. 319
  Ensign D. R. Vankirk Fell at Pensacola. 321
  Melchoir Eberts Fell from Height of 1,500 Feet 352
  David M. Rorer Burned to Death.... 417
  Hetty Nixon Killed in Practice Flight.. 605
Acieral. New note re. Company and Metal Produced 352
Ackerman Wheel Company:
  Aeroplane Wheels, Details of (Art. with line drawings) 455
  Wheels (Illus.) 490
  To Manufacture Aeroplanes (News note) 521
  Aeroplane Wheel Tests (Illus. art.).... 781
  Chassis Connection for Wheels, desc. art. with line drawing.... 833
Acrobatics, Aerial: From an Aeromodellist's Point of View (Model news).607-645
Aerial Coast Protection: See Coast Protection.
Aerial Delivery: See Transportation.
Aerial League of America Organized.... 628
  Participates in State Campaign.... 714
Aerial Mail: See Mail Carrying.
Aerial Paul Revere (News note).... 138
Aerial Reserve Corps:
  Course of Instruction for Student Naval Airmen (Art.) 11
  In Training (News note).... 48
  How You Can Join the Aviation Section, Signal Officers Reserve Corps.... 150
Aerial Route Proposed (News note).... 563
Aero Club of America:
  Executive Board Passes Resolution of Appreciation of Work of Henry Woodhouse 7
  Aircraft Manufacturers and National Advisory Committee Discuss Speeding Up Aircraft Production (Art.).... 74
  Account of Annual Banquet (Edit.).... 101
  Enthusiastic Over President's Message.. 103
  Presents Balloon (News note).... 183
  Offers $10,000 in Liberty Bonds as Prizes 350
  Appoints Foreign Service Committee (News note) 670
  Participates in State Campaign.... 714
  Endorses Hulbert's Work (News note).. 714
  Theodore Roosevelt Endorses Excellent Work of (Edit.).... 767
  Stirs War Spirit of Minneapolis (News note) 914
  Committee Commends Aircraft Production Board and Signal Corps After Inspection of Army Aeronautic Centers (Art.) 962
Aerodrome:
  Mexican Pilots and Aeroplanes at National Aerodrome, Valbuena, Mex.... 226
Aerodynamics:
  Long Tails vs. Short Tails In Art. by Prof. G. H. Bryan, F. R. S. Bangor and S. Brodtesky.... 20
  Experimental Researches on the Resistance of Air, by L. Marchis.... 292
  University of Illinois to Have Laboratory (News note).... 523
  Wind Tunnel for California (News note) 597
  Formation Flying, by F. W. Lanchester. 826
  Risky Flying Weather, by Prof. W. G. Duffield 966
  Formation Flying as Taught by Nature, F. W. Lanchester.... 970
Aero Fund: $2,000 for (News note).... 715
Aerological: Kite Flying at Drexel Station (Model news) 53
Aeromarine Plane & Motor Company:
  Group of Visitors at Plant (Illus.).... 452
  Illus. desc. Training Seaplane.... 454
  Illus. Training Tractor.... 597
  Illus. V. P. Charles F. Willard.... 599
  Illus. Factory 820
  Delivers Seaplane at Bayshore (News note) 865
  Two illus. Hydroaeroplanes Equipped with Torpedo-discharging Apparatus.. 867
Aeronautical Society of America: Judgment Filed Against (News note).... 141
Aeronautics Almost Lost from $115,000,000 Naval Emergency Fund (Edit.).... 5
Aeronitis:
  pp. 25, 54, 84, 116, 156, 196, 228, 264, 298, 333, 364, 396, 430, 466, 500, 539, 575, 608, 645, 685, 737, 789, 837, 884, 931, 981.
Aeroplanes:
  New York Aero Construction Co.'s seaplane (Illus. desc.).... 10

Battleplane with Lewis Machine Gun mounted on bow of car. This plane was the first of its kind in the world

"In my private opinion the Lewis Machine Gun is the best light type gun yet developed for troops in the field."

Major-General LEONARD WOOD,
Commander of the Department of the East.

General Wood stated he "favored having . . . . a reserve supply of 25,000 machine guns as in the end one in ten men will carry a 26 lb. machine gun as he now carries a rifle."

Statement made by Major General Leonard Wood testifying before the Military Committee of the House of Representatives reported in New York World, January 28th, 1916.

Curtiss J. N.
Tractor
Equipped With
Ackerman Wheels

"IT'S IN THE SPOKES"

AFTER four years' exhaustive tests, The Ackerman Wheel Company offers to aeroplane builders a wheel of special design that will solve many of the difficulties hitherto encountered.

In a series of laboratory tests (see illustrations below) the wheel was attached to a large case, into which was loaded 1,500 pounds of sand. A side thrust blow, with the wheel seven feet removed from the point of contact, was calculated to give the wheel a stress of 27,000 pounds. This was when the wheel struck the plain floor surface. To test the wheel to its maximum, two cleats of wood were nailed to the floor, four inches in advance of the striking point, and under this test four spokes of the wheel were broken. Calculation showed that the energy of the blow totalled 49,800 pounds.

A special alloy, specially treated, is used to meet all conditions that the wheel can be subjected to. The steel receives a special process in the treating, so that it will give the required resiliency, starting at the center of the curve and gradually growing stiffer and stronger both to the hub and relative to the structure of the spoke. The spokes being made on the curve, they are hung on the hinge at the rim, being a unit in the hub, allowing them to open and shut according to the load placed on the hub.

In the aeroplane wheel it is found that the hub will leave the center four inches when maximum loaded, and return to center as load is decreased, without the springs taking a set. There has never before been a wheel invented which would meet any such conditions.

These wheels can be built according to size and weight of any load from 500 pounds up to 5 tons

VOL. V NEW YORK, MARCH 19, 1917 No. 1

AERONAUTICS ALMOST LOST FROM $115,000,000 NAVAL EMERGENCY FUND

THE omission of a comma almost eliminated aeronautics from the $115,000,000 Naval Emergency Fund.

Thanks to Senators Poindexter and Lodge, the omission was caught at the eleventh hour, and the Navy Department may now spend whatever is needed to extend the naval aeronautic service out of that appropriation.

We quote the passages from the Senate action which resulted in restoring aeronautics in the Emergency Bill, as it is one of those extraordinary incidents about which one only has read in stories, and it is of utmost importance in showing the eternal vigilance required to protect the development of our aerial defenses. Without that comma the Emergency Fund would be closed to aeronautics and the Navy would be confined to the regular appropriation of $5,130,000, which is far from being sufficient to develop a substantial naval air service.

On March 3d, Senator Swanson laid before the Senate the conference report upon the naval appropriation bill. He had filed the report several hours ago, so that Senators who were interested might find what action has been taken by the House and Senate conferees. The Secretary proceeded to read the report. During the reading the following took place:

Mr. POINDEXTER. Mr. President, I should like to ask the Senator from Virginia what the purpose of the conferees was in changing the emergency appropriation of $115,000,000 so as to eliminate aircraft from the purposes for which it could be used, among others?

Mr. SWANSON. I will say to the Senator that the report does not do that. It increases the use.

Mr. POINDEXTER. Mr. President, the report does do that. It has the peculiar effect of authorizing the purchase of ammunition for aircraft without authorizing the purchase of aircraft.

Mr. SWANSON. No.

Mr. POINDEXTER. The original language of the emergency-fund appropriation did authorize the purchase of aircraft. This one does not. I regret it very much. I only desire to call attention to it. I do not desire to impede the adoption of the conference report for that reason, but simply to call attention to that omission and to express great regret that the conferees have omitted that from the provision, for the reason that aircraft are of constantly increasing importance—one of the greatest needs, in fact, in the enlargement of naval equipment.

Mr. SWANSON. If the Senator will examine the report he will find that he is entirely mistaken.

Mr. POINDEXTER. I am not mistaken, Mr. President. I have head the provision with the greatest care, and I am perfectly competent to understand what the language of it means.

Mr. LODGE. In the amendment to amendment No. 85 there is a word left out by mistake.

Mr. POINDEXTER. It does not provide for aircraft.

Mr. LODGE. It has been left out by mistake. We can correct it by a resolution.

Mr. SWANSON. Let the Secretary read it again.

The Secretary read as follows:

"That the House recede from its disagreement to the amendment of the Senate No. 85 and agree to the same with an amendment as follows: Strike out said amendment and insert:

NAVAL EMERGENCY FUND

"To enable the President to secure the more economical and expeditious delivery of materials, equipment and munitions and secure the more expeditious construction of ships authorized and for the purchase or construction of such additional torpedo boat destroyers, submarine chasers and such other naval small craft, including aircraft guns and ammunition for all of said vessels and aircrafts and for each and every purpose connected therewith, as the President may direct, to be expended at the direction and in the discretion of the President, $115,000,000, or so much thereof as may be necessary, and to be immediately available."

Mr. SWANSON. The only mistake is that there should be a comma after "aircraft," so as to read "aircraft, guns and ammunition." If a comma is put in there, it will make it entirely correct.

The Secretary read as follows:

"Including aircraft, guns and ammunition."

Mr. SWANSON. The purpose is to furnish guns and also ammunition for the aircraft. There was a comma left out. I ask unanimous consent that the unfinished business be temporarily laid aside and that we proceed to dispose of the conference report.

The PRESIDENT pro tempore. Is there objection. The Chair hears none. So the Emergency Appropriation was made available for aeronautics.

VOLUNTEER AERIAL COAST PATROL UNIT No. 2 FORMED

A SECOND volunteer unit of the Aerial Coast Patrol has been formed by prominent young men now completing their course at the Yale University.

Volunteer Aerial Coast Patrol Unit No. 2, as this new unit will be called, has been established with Messrs. G. E. Depew and Frank Goodyear, of Buffalo, as the heads, and through the cooperation of Mr. Robert A. Lovett, son of Judge Robert Lovett, the President of the Union Pacific Railroad, who is a member of Volunteer Aerial Coast Patrol Unit No. 1, of which F. Trubes Davison and H. P. Davison, Jr., sons of H. P. Davison, of J. P. Morgan & Co., Artemus L. Gates, the captain of the Yale team, and eight other prominent young men, are members.

The valuable work of Aerial Coast Patrol Unit No. 1 during the Mosquito Fleet Manoeuvres of last year made it a most distinguished unit, and in the present national crisis, scores of red-blooded Yale men who wish to prepare themselves so as to be of use to meet an emergency have applied for admission in the Aerial Coast Patrol Unit. There are now close to 30 members to Volunteer Aerial Coast Patrol Unit No. 1 who are ready to leave the Yale University in the event of a declaration of war and start training in the operation of seaplanes.

The new Volunteer Aerial Coast Patrol Unit No. 2 will have the cooperation and assistance of Unit No. 1, and Mr. Robert A. Lovett of Unit No. 1 will supervise the training.

The following general arrangements are given in the statement of the organizers of Volunteer Aerial Coast Patrol Unit No. 2 to Real Admiral Robert E. Peary, Chairman of the Aerial Coast Patrol Commission:

1. *Formation:* The Second Unit of the Aerial Coast Patrol has been established with Messrs. G. G. Depew and Frank Goodyear of Buffalo as the heads, and through the cooperation of Robert A. Lovett of the 1st Unit of Aerial Coast Patrol.

2. *Personnel:* Eight men have been chosen as being particularly fitted for such work. These are ready for instant service in case of war. The number will be increased as pilots are graduated.

3. *Training:* a. Model "F" Curtiss boats will be used for the first period of training. The schooling machine is ready for immediate shipment to the training quarters.

b. Instructions will be given by an expert water-flier, and assistance by amateurs.

c. The Jekyl Island Club of Brunswick, Ga., has been kind enough to place its equipment at our service, and the location is ideal for schooling and experimenting, since the island is privately owned and the bay secluded.

d. In the event of war not coming before the close of college, training will be given on Lake Erie with the assistance of the Curtiss Company.

4. *Machines:* In case of need the "F" boat will immediately be shipped to Jekyl Island. These machines will be added, two of the pontoon type to meet the practice of the Navy Department.

5. Instruction in navigation and wireless will start here in New Haven and be continued regardless of the course of national events.

6. Prominent Buffalo men will act as advisers.

7. *Plan:* In the event of a declaration of war or upon notification that our services would be of assistance to the Navy, we are ready to leave at once and start training. Arrangements have been made with the college authorities, and everything else is ready for instant mobilization.

The officials of the Aerial Coast Patrol Commission are: Real Admiral Robert E. Peary, Chairman; Senator Charles F. Johnson, Senator Morris Sheppard, Representative Julius Kahn, Representative Charles Lieb, Representative Murray Hulbert, Hon. Byron R. Newton, Asst. Secry. of the Treas., Hon. William M. Ingraham, Asst. Secy. of War., Dr. E. Lester Jones, Supt. U. S. Coast & Geodetic Survey, Dr. H. C. Frankenfield, Chief Forecaster, U. S. Weather Bureau, Hon. Emerson McMillin, Mr. John Hays Hammond, Jr., Member Board of Governors, Aero Club of America, Mr. Alan R. Hawley, Pres., Aero Club of America; Mr. Henry Woodhouse, member, Board of Governors, Aero Club of America.

Panama Defences and Aircraft

(Editorial in New York *Sun*)

THE prompt response of General Goethals to the very definite assertions recently made by Mr. Rex Beach that the Panama Canal is without adequate defence in time of war will go far to restore public confidence. It will be remembered that prior to his assignment to duty at Panama General Goethals, then Colonel, was a distinguished member of the National Board of Fortifications, and his opinion on so technical a subject as the adequacy of the canal's defences should be promptly accepted even against that of a successful literary man.

The point at which the General concedes weakness in the canal's defences is in the provision for aeroplanes and anti-aircraft guns. This weakness, however, is common to all our defences, even those of New York. The United States, home of the inventors of the modern aeroplane, has of all nations been last to recognize the value of aircraft in military and naval operations. There are more planes today used as playthings by our young millionaires than are at the command of our two armed services. There are more American boys flying in France, risking and giving up their lives in the cause of the Allies, than are carried on the rolls of the aviation corps at home.

This condition will be remedied now that the navy bill has appropriated $5,000,000 for aviation purposes and permits the use of further sums from the $115,000,000 emergency fund. It is fortunate that aircraft, unlike ships, can be built in a few weeks, and that the training of a skilled pilot can be perfected in from four to six months, as demonstrated in the military training schools of Europe.

The Secretary of the Navy, being now provided with funds and authority, should lose no time in beginning the creation of an effective aviation corps—for despite a few machines and pilots now in service, systematic work to that end cannot be said to have begun.

Leading Organizations Endorse Plan to Get 5,000 Aviators for National Defense

The Rotary Club, the Georgia Technology Club of New York, the Pennsylvania University Club of New York, The Traffic Club, the Alumni of the Packer Institute and Brooklyn Heights Seminary, are among the organizations addressed on the subject of aerial preparedness by Mr. Henry Woodhouse in the past two weeks.

While the text of the address delivered at each was different, the part dealing with the necessity of upbuilding our aerial defenses concluded each time with the vital necessity of getting and training 5,000 aviators for national defense. The sugestion is always received with rousing applause and expression of endorsement.

Of the address delivered by Mr. Woodhouse to the Rotary Club on March 8th, the Brooklyn *Times* says:

Henry Woodhouse, managing editor of Flying and governor of the Aero Club of America, recognized as the best informed man on aeronautics in this country was the principal guest and speaker today at the luncheon of the Rotary Club at the Bossert. It was also entirely through the efforts of Mr. Woodhouse, under the authority of Alan R. Hawley, president of the Aero Club that the recent National Aeroplane Fund was created out of which grew the appropriations by Congress of seventeen million dollars for equipping the army and navy with aeroplanes and training aviators.

Mr. Woodhouse said in part:

"The army and navy, which has the best air fighters, holds the supremacy of the air, and while being able to get information about every movement of the enemy, have it in their power to prevent the enemy from getting any information. That may be said to be responsible for all the victories of the present war.

"The nations are making frantic efforts to increase the number of their aeroplanes and aviators. It is known that England, Germany and France have over 10,000 aviators each, one-third of whom are in daily service. Every effort is being made to increase their number, also the number of aeroplanes, dirigibles, observation balloons and anti-aircraft defenses.

"It has been estimated that England spent $250,000,000 on her air service during the last twelve months. The Royal Flying Corps alone has about 350 officers. There are 107 aeronautic stations in Great Britain alone, and the personnel of the British and Naval Flying Corps is said to employ about 500,000 men. Canada has a budget of $80,000,000 to be spent on aeronautics and has just ordered 200 aeroplanes.

"I would like to touch upon the development of the torpedoplane which makes it possible for a $20,000 device to be a worthy match for a $20,000,000 battle cruiser.

"It is not possible to go at length into the employment of aeroplanes for submarine warfare and to give a description of scientific instruments developed, the higher development of the science of aerial photography, the value of dirigibles and observation balloons as auxiliaries for the navy and the development of aerial gunnery.

"An idea of America's share in making aeronautics what it is today can be had from the recent cable despatch from England, in which it was stated that an American-made machine had carried eight persons, 600 gallons of gasoline, guns, ammunition and other equipment, and had made a speed of 78 miles an hour; also from the fact that the best aeroplane guns and instruments are American inventions."

EXECUTIVE BOARD OF THE AERO CLUB OF AMERICA PASSES RESOLUTION OF APPRECIATION OF WORK OF HENRY WOODHOUSE

THE Executive Committee of the Aero Club of America, at its March 7th meeting, unanimously adopted the following resolution:

WHEREAS, Mr. Henry Woodhouse, having, in the opinion of the Governors of the Aero Club of America, earned an acknowledgment of their appreciation of his extraordinary achievements on behalf of the aeronautical movement, the movement for national preparedness for defense, and the club, and

WHEREAS, the many undertakings initiated and so successfully carried out by Mr. Woodhouse and his associates having proven of great value to the aforesaid movements, and the club, and

WHEREAS, among these activities should be mentioned the following:

The creation of the Pan-American Aeronautic Federation, by means of which the sportsmen of the Americas have been united in a common undertaking of great usefulness;

The creation and successful conduct of the National Aeroplane Fund, by means of which the American aeronautic industry when at its lowest ebb was revived, and the public aroused to the need of active military and naval aeronautic preparation;

The stimulation of Congress to vastly increase its aeronautical appropriations;

The instigation of the movement to interest college students in aerial defense, and the development of aeronautics;

The establishment and successful conduct of the recent Pan-American Aeronautic Show;

Together with other services which he has rendered, and

WHEREAS, by these activities and his untiring devotion to the cause for which the Aero Club of America stands, and to his colleagues, Mr. Henry Woodhouse has won the admiration and esteem of his fellow governors, therefore

BE IT RESOLVED: That the Board of Governors of the Aero Club of America hereby tenders to Mr. Henry Woodhouse its thanks, and this expression of its appreciation of the invaluable services which he has rendered to the nation, the aeronautic movement, and the club.

Henry Woodhouse

Mr. Woodhouse is a Most Useful Citizen

Mr. Woodhouse has given sixteen hours daily to developing aeronautics for the past six years. Before that, for a number of years, he gave from four to six hours daily. Although only 33 years old, he has traveled widely. According to the biography printed in the National Cyclopedia, Mr. Woodhouse was born in Turin, Italy, being the son of a prominent manufacturer. He early developed a taste for literary work, and having traveled extensively through France, Switzerland, England, Belgium and Italy, he improved every opportunity for studying modern languages and science, especially economics, sociology and aeronautics. He came to the United States in 1904 and took out his naturalization papers in 1909. Almost immediately after his arrival in this country he became a contributor to such periodicals as *Collier's Weekly, McClures, Metropolitan, The Independent* and *World's Work.*

There was a growing demand for articles on aeronautics, the development of which he had followed since boyhood, and he wrote largely on that topic, in one year averaging 3,000 words a day for the entire year. In 1911, with Robert J. Collier and Henry A. Wise Wood, he founded the aeronautical monthly magazine *Flying,* of which he became managing editor. He contributed to *Flying* many instructive and timely articles; he prophesied the development of military aeronautics, the extensive employment of aeroplanes by armies and navies in future wars, and the development of the hydroaeroplane, with which Glenn H. Curtiss had just begun to experiment. Being a deep student in economics and sociology, he pointed out the uses of aircraft to solve problems of transportation. As early as 1912 he urged the employment of aeroplanes as mail carriers between points inaccessible by rail. The science was then in its infancy; fatal accidents were numerous, and the general public was skeptical of the practicability of aviation. The aeronautical authorities of the country told him he was ahead of his time, and his associates advocated the suspension of *Flying,* but Mr. Woodhouse was firm in his belief that the aeroplane had come to stay. He had the courage of his convictions and continued the periodical at his own expense. He decided to go on until $20,000 of the $25,000 which he had was spent. *Flying* is today the foremost authority on the subject of aviation in the United States.

Always well-informed, optimistic and far-seeing, he rendered valuable service to the science by encouraging and advising inventors, aviators and workers in the aeronautical field. His early articles on military aeronautics stand as prophecies fulfilled. He had made a careful study of the military institutions in the United States and Europe. What appeared to be over-estimation in 1910-13 regarding the value of the aeroplane for military service, reads today like sane interpretations of the trend of events.

The happy processions of a wonderfully resourceful mind, and an everlasting desire to be of service to the world in general, he has the remarkable faculty of being able to consider the problems of a dozen people who may come to consult with him and to quickly analyze their baffling problems and suggest solutions for them. As a result his advice is sought widely and for most important matters. His advice is always free—but if it is not about aeronautics he promptly introduces aeronautics in the subject or plan in some way. This has resulted in creating interest in aeronautics in practically every line of human endeavor.

Besides being a fluent writer Mr. Woodhouse is a fluent speaker and delivers several addresses to organizations each week.

His practical support to the aeronautic movement has been as substantial as his moral support. Mr. Woodhouse never asks anybody to do what he would not do himself, therefore he begins by doing it himself. If there is a bill to be footed for expenses for developing something worth while, he begins by subscribing himself. For instance, he paid all the expenses of developing the Pan-American movement since 1911, and subscribed the first $1000 for the preliminary expense of holding the First Pan-American Aeronautic Exposition. When he founded the National Aeroplane Fund, he subscribed the first $1000, and continued giving to the Fund in different ways for eighteen months. Another of the many instances, Mr. Woodhouse started the fund for the training of Observation Balloon Operations with a personal contribution of $250; and there are men under training for the U. S. Army Aerial Reserve Corps whose expenses to "get there" were paid by Mr. Woodhouse.

Like Mr. Alan R. Hawley, Henry A. Wise Wood, Rear Admiral Peary and the other leaders of the aeronautic movement, Mr. Woodhouse has received and receives a great many offers to participate in commercial enterprises. It is quite logical that people who have been financed or have secured business amounting to hundreds of thousands of dollars should offer commissions to those who assisted or advised them. Such offers are duly and firmly declined. Those who make the offers are invited to "forget it," but to do for others, if the opportunity presents itself, as has been done for them.

His aim and motto is to do "what is the best for the largest number of people, for the longest time."

Before the European war Mr. Woodhouse was an active peace worker and wrote articles and delivered addresses on the subject, expressing his belief that the factors which would bring world-peace would be aerial transportation and wireless intercommunication, causing the intermixing of people and their interests, just as the railroad, telegraph and the telephone brought more closely together the people of the North and the South of the United States, thereby eliminating the differences caused by the Civil War. But in 1913 he saw indications of a coming conflict and started to urge national preparedness. In August, 1913, he contributed a prophetic article to *Flying* entitled "The Empire of the Air," which gave the air strength of the nations at the time. This article concluded as follows:

"The United States is the only country that is not contesting for the empire of the air. Far from it, it has not even as yet recognized the potentiality and economy of aerial armament. The Army and Navy combined have just a score of aeroplanes, of which half are old training machines, many dangerously worn; of dirigibles we have none. And we have no equivalent for these, either, our mobile army counting just 90,000 soldiers, and our navy having just stepped back one step and taken fourth position. This big, prosperous country is, therefore, open to attack and undefended. At present we are, by strenuous efforts and large expense in diplomatic negotiations, at peace with the world; how long that will last is a problem. With the alarming economic conditions in Europe, continuous warfare among our neighbors, the general aggressive spirit of nations, it rather seems that we ought to be as alarmed as Great Britain is."

Since then he has been an ardent advocate of the National Defense movement, and was active in urging upon the American public by voice and pen the seriousness and importance of a stronger national defense. He was the founder of the National Aeroplane Fund; a permanent delegate to the Conference Committee on National Preparedness, and a member of the Committee of One Thousand appointed by Mayor Mitchel of New York. In 1915 he founded the AERIAL AGE, a weekly, and he is president of the Aerial Age Co., Inc., and also the Flying Association, Inc. In 1916 he founded *The Aeronautic Library* and the *Aeronautic Photo and News Service*. He is a governor of the Aero Club of America, was the founder and a director of the American Society of Aeronautical Engineers, which has been merged with the Automobile Engineers; is Educational and Industrial delegate, Pan-American Aeronautic Federation; a member of the National Aerial Coast Patrol Commission, the Economic Club, the American Association for the Advancement of Science, the National Arts Club; a councillor of the American Civic Association; member of the Ways and Means Committee of the World's Court League, a governor of the Patriotic Educational Society, a governor of the National Institute of Efficiency, and also a member of the Society Automobile Engineers, American Academy of Political and Social Science, the National Press Club, the Authors' League of America, the League for Political Education, the League to Enforce Peace, the National Geographical Society, the American Red Cross, the Twilight Club, the Navy League, the National Security League, the Merchants Association of New York, the American Forestry Association, and an honorary member of the Aero Club of New England. He was a delegate to the second Pan-American Scientific Congress in 1916; also delegate from New York, apointed by Governor Charles S. Whitman, to the Congress of Constructive Patriotism, Washington, January, 1917; and to the American Civic Federation Convention.

Last week he was appointed secretary of the Central Committee on Aeronautics, which is co-operating with the Commandant of the Third Naval District in organizing the Naval Reserve Force, and chairman of the sub-committee on equipment.

THE NEWS OF THE WEEK

U. S. Navy Orders 16 Dirigibles

WASHINGTON, March 12.—Purchase of sixteen non-rigid dirigible airships for coast and harbor patrol work, at a total cost of $649,250, was announced to-day by the Navy Department.

The Curtiss Aeroplane Company of Buffalo was awarded three for $122,250; the Connecticut Aircraft Company, New Haven, two for $84,000; the Goodyear Tire and Rubber Company, Akron, Ohio, nine for $360,000, and the B. F. Goodrich Company of Akron two for $83,000. Deliveries will begin within 120 days.

The airships are the first of such type to be bought by the navy. They will be 160 feet in length, 31½ feet in diameter or 50 feet high over all, will be equipped with radio communication and 100 horsepower motors capable of making a continuous flight of sixteen hours at thirty-five miles each and a maximum speed of forty-five miles an hour for ten hours.

Aeroplanes Seek Surveyors Lost in Florida Swamps

Jacksonville, Fla.—Aeroplanes are skimming the Everglades searching for three New York engineers who are believed to be lost.

The party consisted of John W. King, his son, John W. King, Jr., and William Gattlow. They had been doing much survey work in the Everglades during the winter, and four weeks ago left Miami by boat to investigate the Tamiami Trail.

The boat carried provisions for three weeks, and the party was to have returned to Miami a week ago Saturday at the latest. Several days passed, and when they did not arrive, several Seminoles were sent out on the trail. They penetrated twenty miles into the swamp and found nothing.

When they reported no success the Curtiss Aviation School was consulted, and Philip Rader, chief instructor, made three wide-sweeping flights over the Everglades, with a passenger always looking down into the swamp and jungle. hoping to get sight of the three lost engineers. Other aeroplanes have been sent out, all of them keeping close to the ground, but nothing has been seen of the lost men. The search is being continued.

Aero Club Banquet to be Held at Waldorf-Astoria

New York.—The annual banquet of the Aero Club of America is to be held this year at the Waldorf-Astoria on the evening of March 30

Export of Aeroplanes

New York.—Since our last report the export of aeroplanes and parts have been as follows: To Great Britain, $78,322; to Bermuda, $34; total, $78,356.

Examination for Navy Aero Post

Washington.—There is a vacancy in the Navy Yard for a graduate of some recognized technical school or university who has had five years' experience and who can satisfy the requirements. The pay is $4,000 per year.

The duties of the job consist in the direction and interpretation of tasks of aeronautical engines and the design of engines and research work. The applicant should have a broad training in engineering and mathematics.

The examination will be conducted on March 20.

Sentries to Shoot Air Spies

San Francisco.—Sentries are under orders to shoot to kill any aviator flying over the fortifications of this port. The order was issued by Major-Gen. J. Franklin Bell, commander of the Western division of the army, after an aeroplane was observed yesterday flying over Forts Miley and Winfield Scott.

The airman, traced to his hangar in Alameda, across the bay, was discovered to be Jacob R. Struble, a wealthy engineer and amateur aviator, who said that if he had violated a warning issued ten days ago by army officers for aeroplanes to keep away from coast military reservations he had done so unwittingly.

Seven Military Planes in Flight at San Diego

San Diego, Cal., March 7.—A squadron of seven military aeroplanes, led by Lieutenant R. L. Taylor, of the Connecticut National Guard, flew from the Signal Corps Aviation School, at North Island, to Los Angeles and return to-day. The aeroplanes, flying in fleet formation, flew at an average altitude of six thousand feet and at an average speed of seventy miles an hour.

Lieutenant W. A. Robertson, who was lost for nine days in the Sororo desert with Colonel Harry Bishop when they lost their bearings while on a flight from San Diego to Calixco, January 10, acted as rear guard for to-day's cross-country jaunt.

The flight was made as a test for the first 1917 class of junior military aviators. Those who handled the control wheels in addition to Lieutenants Taylor and Robertson were aviation students Lieutenants Benjamin Wier, B. W. Mills, H. B. Anderson, E. L. Naiden, George Pulsifer, B. F. Byrom, J. T. McNarney, W. W. Winne, C. W. Howard and Thomas Hanley.

Lieutenant Taylor, piloting the Curtiss tractor No. 61, ascended at half-past seven A. M., the remaining six aeroplanes then ascended at five minute intervals. Forming in fleet formation over Point Loma the flotilla headed for Los Angeles, landing at Dominguez field at nine o'clock. At Los Angeles the five aviators who did not pilot machines on the flight north were given the control wheels for the southbound air voyage. Lieutenant Taylor landed at North Island at half-past twelve P. M. He will complete his graduating tests tomorrow, and will have the distinction of being the first National Guardsman to graduate from the signal corps aviation school with the rank of junior military aviator. He has been under instruction less than ninety days.

Lieutenant Millard F. Harmon, one of the army aviators ordered to France for flying duty with the French flying corps, was married to-day. His bride was Miss Alberta B. Clark, daughter of Charles A. Clark, director of the American Hardware and Plumbing Company, of Maila.

Mrs. H. P. Whitney Flies from Palm Beach to Miami

Miami, Fla., March 7.—Mrs. Henry Payne Whitney and Mr. Henry Worthington Bull flew from Palm Beach to-night in an aeroplane and joined Mr. Whitney on board his yacht the Whileaway. They made the trip of seventy-two miles in an hour.

While this was not Mrs. Whitney's first trip in an aeroplane, it is the longest one she ever had made. She was enthusiastic over the experience.

Hawaiian Aviation Activities

Honolulu.—Modern advances in "preparedness" are cleverly shown on the float entered by the Aero Club of Hawaii in the Preparedness Parade. The setting is the wireless station at Pearl Harbor, Uncle Sam's great landlocked fortress, with the three huge masts towering above the lochs. In the waters of the lochs rides a grim-looking battleship, and above soars a miniature aeroplane.

The aeroplane was constructed under the direction of Lieut. R. C. Holliday, secretary of the Aero Club of Hawaii. It is a faithful model of a Curtiss J.N.4 tractor biplane, finished in the dun-color of the modern plane, and has a miniature flyer operating it. The propeller is attached to a motor operated as the float moves. The biplane is one-tenth natural size. This entry, depicting the most modern of modern inventions, proved a striking contrast to the scenes from ancient Hawaii which passed in advance.

The Aero Club of Hawaii were guests at a luncheon given by the Honolulu Commercial Club in the club rooms of the latter organization.

Tables were laid for more than three hundred guests.

General F. S. Strong, president of the Aero Club, introduced Mr. Clifford Harmon of New York who spoke very interestingly on the subject of "Aviation, Past, Present and Future." At the conclusion of his remarks, General Strong thanked Mr. Harmon for his courtesy in addressing the two clubs, and the Commercial Club for the generous spirit shown by them in affording the members of the Aero Club the opportunity of hearing Mr. Harmon's interesting remarks.

Captain John F. Curry, Aviation Section, Signal Corps, arrived on the February transport from San Francisco and has taken up the work of preparing the ground for the arrival of the equipment and personnel for the Sixth Aero Squadron which he is to command.

The equipment is expected to arrive in the Islands in April or May of this year.

Army and Navy News

Sergt. James R. Graham, of the Signal Enlisted Reserve Corps, is assigned to active duty in the Aviation Section, Signal Enlisted Reserve Corps, with station at the Curtiss Aviation School, Miami, Fla., Feb. 24, 1917. (Feb. 24, War D.)

Sergt. Samuel B. Eckert, Signal Enlisted Reserve Corps, Fort Monroe, Va., to active duty in the Aviation Section, Signal E.R.C., with station at the Curtiss Aviation school, Newport News, Va., Feb. 26, 1917. (Feb. 26, War D.)

Under the provisions of the National Defense Act, approved June 3, 1916, the 3d Aero Squadron, Signal Corps, will be organized near San Antonio, Texas. The commanding general, Southern Department, will complete the organization by assigning to this squadron enlisted men of the Aviation Section now in or to be sent to his department.

1st Aero Squadron.—Columbus, N. M.

2d Aero Squadron.—1st Co. Fort Mills, P. I.

3d Aero Squadron.—Fort Sam Houston, Texas.

Aviation.—Cos. A, San Diego, Cal.; B, Mineola, L. I., N. Y.; C, Memphis, Tenn.; D. Fort Sam Houston, Texas; E. Fort Omaha, Neb.

Major Benjamin D. Foulois, junior military aviator, Signal Corps, from duty in Southern Department and will report to commanding general of that department for duty to accompany troops to a point nearest Washington, and then repair to Washington for duty in office of Chief Signal Officer. (March 6, War D.)

Capt. Townsend F. Dodd, junior military aviator, Signal Corps, from duty at Columbus, N. M., to San Antonio, Texas, for duty as department aviation officer, relieving Capt. Benj. Foulois, S. C. (March 6, War. D.)

Signal Enlisted Reserve Corps

Sergt. William E. Lewis, S. E. R. C., to active duty in Aviation Section at the Curtiss Aviation School, Newport News, Va., March 6. (March 6, War D.)

Sergt. Leon Richardson, S. E. R. C., to active duty in Aviation Section at the Curtiss Aviation School, Newport News, Va., March 6, 1917. (March 6, War D.)

The following sergeants of S. E. R. C. to active duty in Aviation Section at the Curtiss Aviation School, Miami, Fla., March 6, 1917: William J. Foy, Frank D. Croxford, Augustus F. Horn and William B. Rodgers, jr. (March 6, War D.)

Sergt. Lloyd L. Harvey, S. E. R. C., to active duty in the Aviation Section at the Curtiss Aviation School, Newport News, Va., March 6. (March 6, War D.)

Sergts. William G. Schauffler and Harold M. Gallop, S. E. R. C., from active duty in the Aviation Section at the Curtiss Aviation School, Newport News, Va., March 10, to their homes. (March 6, War D.)

Sergt. Christopher C. Cole, of the S. E. R. C., to active duty in Aviation Section at Signal Corps Aviation School, San Diego, Cal., March 10. (March 6, War D.)

The following sergeants of the Signal Enlisted Reserve Corps are assigned to active duty at the Curtiss Aviation School, Miami, Fla., March 6: Henry A. Theed and George E. Olmsted. (March 3, War D.)

The following sergeants of the Signal Enlisted Reserve Corps are assigned to active duty at the Curtiss Aviation School, Newport News, Va., to take effect March 6, 1917: Cecil G. Sellers, John A. Hambleton and Harry M. McCuistion. (March 3, War D.)

The following sergeants of the Signal Enlisted Reserve Corps are assigned to active duty in the Aviation Section, Signal Enlisted Reserve Corps, with station at the Curtiss Aviation School, Newport News, Va., March 6, 1917: David H. Young, Thomas E. P. Rice, Alexander H. Williams, jr., and William A. Munn. (March 6, War D.)

Triplane Success Established

The enthusiastic preliminary report made by Capt. William G. Ocker, Aviation Section, Signal Officers' Reserve Corps, after his experiments with the new triplane at the Newport News (Va.) Aviation School, has been borne out by later and more complete tests, it is learned. As a result four machines of this type have been ordered for immediate delivery to as many schools and it is more than probable that seventy triplanes—enough for two coast defense squadrons—will be secured in the near future. Some officers connected with the Aviation Section are so convinced of the superiority of the new design tually it will supplant the biplane as the main reliance of our air service. These officers (they are all qualified to speak as aeronautic experts), are at a loss to explain the persistency with which the French government has clung to the monoplane, in view of the fact that experiments here seemed to fully demonstrates the superiority of the biplane over that type in everything except speed; and now the biplane appears to be about superseded.

Capt. F. T. Evans, of the Aeronautic Station at Pensacola, who recently looped in a seaplane.

Captain Ocker's experiments are being continued at the Virginia school. When this duty is concluded he will be assigned as assistant to Robert Glendenning, the wealthy Philadelphia aviator who is to be made a major in the Signal Officers' Reserve Corps, and placed in charge of a military aviation school to be established at Essington, Pa.

Army Airmen to Go to France

Major William Mitchell, of the Aviation Section, Signal Corps, with Lieut. Joseph E. Carberry, of the same section, and Lieuts. Millard F. Harmon, jr., and Davenport Johnson, who have been detailed from the Infantry to duty with the 1st Aero Squadron at Columbus, N. M., will sail from New York on March 20 for Paris to act as "aviation observers" on the French front. Since the beginning of the war the French government has repeatedly invited our War Department to send over young aviation officers who could study at first hand the great strides made in that arm of the service in recent years. The four officers will look particularly into the organization of the French aviation service behind the front.

Major Benjamin D. Foulois, junior military aviator, Signal Corps, U. S. A., now in command of the air squadron at San Antonio, Texas, that they do not hesitate to predict that even-with the title of "department aviation officer," has been ordered to Washington to take the position in the headquarters of the Aviation Section left vacant by Major William Mitchell, detailed as observer in France. Major Foulois's place will be taken by Capt. Townsend F. Dodd, also a junior military aviator in the Signal Corps. Orders relieving Captain Dodd from duty at Columbus, N. M., were published March 8.

Capt. H. A. Dargue, U. S. A. aviator, and Emil J. Simon, government radio engineer, at San Diego, Cal.

Fifty enlisted men from the U. S. Army Aviation Training School, at San Diego, Cal., left on February 28 for San Francisco, from which port they were to sail on the transport Sheridan for Honolulu, where they will be stationed with the Seventh Aero Squadron. This squadron, a seaplane unit, will comprise eighteen skilled aviators and about 160 men when recruited to full strength. Sixteen seaplanes are to form the flying equipment of the squadron, which will be commanded by Capt. John F. Curry, U. S. A. The first of these machines is expected to reach Honolulu about May 1. Fifty more mechanicians from North Island as the nucleus for the 6th Aero Squadron for duty at Panama will leave for the Canal zone this month.

Government Prepares to Take Over San Diego Site

United States District Attorney Schoonover is preparing the abstract of the land recently purchased by the United States, at San Diego, for headquarters of the aviation service on the Pacific Coast. The land consists of 237 acres, lying on what is known as Dutch Flat, at the north end of San Diego Bay, and an appropriation of $250,000 has just been made by Congress. The property has been purchased of the San Diego Securities Company. With the completion of the abstract, the title to the land will pass to the government.

The Bridgeport Aviation Corps

Bridgeport, Conn., March 14.—That the great number of applicants for admission to the aeronautic section of the Third Division, Connecticut Naval Reserves, has made the formation of a second section here necessary, that four Connecticut men headed by a Bridgeport manufacturer are in training at Pensacola, Florida, and that the state has given a huge plot of ground at Westport to the corps to be used as an aviation field, were among the facts announced to-day by Lieutenant Albert J. Merritt, who has charge of the aviation work of the reserves.

With the formation of a second section there will be 46 men and 11 officers engaged in aviation work in connection with the naval reserves. Four fliers have been promised by the government, three more by private owners who are members of the corps, and it is planned to raise enough money to buy a fully equipped scout cruiser.

Considerable difficulty was experienced in obtaining a suitable field. But this problem was solved when a search of land records revealed that the state owned a huge site on the shore of the harbor near Westport. It had not been used in many years, and had been generally forgotten.

The plot is cut up by a few small strips of private land, but these immediately will be condemned and taken over by the state. A grant of all this land has been given the aviation corps, and work on the erection of hangars and barracks will be started in the near future.

Aero Club for Mass. Tech.

Interest in preparedness at the Massachusetts Institute of Technology took concrete form on March 6, when, at a meeting attended by more than 200 students, it was decided to form an aero club and offer its services to the United States in the event of war. A committee of five—Capt. E. S. Gorrell, U. S. A., instructor at the Institute; P. D. Scheeline, E. P. Warner '17, John Braisten '18 and C H. Tavener '18—will draw up a constitution for the organization, which is to hold its first meeting in the course of the coming week.

Capt. Gorrell was asked to deliver an address. He informed the students that he would talk to them in an unofficial capacity, and then told them it was the purpose of the United States War Department to establish aero training schools for civilians.

He made an earnest plea for the aviation corps. He declared that the service is a most attractive one, and urged all possible to interest themselves in it.

The students were informed that it would be the endeavor of the War Department to so conduct the camps that they would not interfere with the school work. The students were also told that those who qualified would be given commissions as first lieutenants in the officers' reserve corps.

E. P. Warner of the faculty outlined the prospects in aeronautical work. He urged the students in that branch of engineering to give careful weight to the problem, and said that work in the club would be valuable from a patriotic as well as a professional standpoint.

Ellehammer Visits Orville Wright

I. C. H. Ellehammer, of Copenhagen, Denmark, one of the pioneers of aviation in Europe, recently visited Orville Wright in Dayton. The Copenhagen inventor comes with the design of a new motor for which he has very great expectations.

MINEOLA DEVELOPING AS AN AVIATION CENTER

THE Army Aviation Field at Mineola, Long Island, which a year ago was known essentially as the place where a score of National Guardsmen were training with funds raised by the Aero Club of America is developing and becoming an important military aviation center.

So far, it has been a school for preliminary training, but arrangements are now being made to teach the students in the most modern methods of both offensive and defensive aerial combat. There are fourteen aeroplanes and the twenty-two students include six student instructors and members of the Aerial Reserve Corps and of the First Aero Corps, N. Y. N. G., and the Signal Corps, U. S. A., and twenty-four more will be added soon.

Three weeks ago there was announced by the military authorities that fifty machines and 250 students would be sent to Mineola within a week. Machines have been sent, but not the students. Therefore, the six senior instructors are still practically idle. The weather is, of course, unsuited for preliminary flying training, but the students could be taught the rudiments, of aerodynamics, aeroplane and motor construction, instruments, meteorology, etc.

Additional buildings are needed to accommodate additional students and that, more than anything else, is holding up progress. During the last part of the Summer and Fall it was failure on the part of the Washington office of the U. S. Aviation Section to send students to be trained. They had hundreds of applications from men anxious to join the Aerial Reserve Corps, but the administrative staff was not sufficient to attend to the applications.

Captain Joseph E. Carberry is in charge of the Mineola field, assisted by Captain W. G. Kilner and Captain Shepler W. Fitzgerald.

The six senior instructors are: Bert Acosta, Archibald L. Allen, W. Leonard Bonney, A. W. Briggs, P. C. Millman and M. Bjorklund.

These instructors, like the officers in charge fly at every opportunity, under severest conditions. A few days ago Bonney looped the loop four times in rather severe weather.

Everything is done at Mineola that can possibly be done under the restrictions imposed by circumstances. For teaching the modern methods of both offensive and defensive aerial combat, as it is planned, there will be required fast pursuit machines, which have a speed of close to 120 miles an hour, and the large types of battleplanes, or bomb carriers, which are armed actually passed the Reserve Military Aviators' to fight off the attacks of pursuit machines. Also aeroplane guns, long distance wireless sets, etc. No pursuit machines have as yet been delivered; and there is only one battleplane available, the twin-motored Curtiss biplane equipped with the Sperry stabilizer, which enables the pilot to let go of the controls to manoeuver the gun. There are not yet any aeroplane guns available at Mineola, nor long distance wireless sets. Nor are there observation balloons or training dirigibles.

Every opportunity is taken to do constructive work and conduct experiments of educational importance. Recently a film was taken to illustrate the training of aviators. Among the problems devised for the advanced students, these problems comprise methods of recognizance both visual and photographic.

In order to simulate conditions of actual combat in the air, Captain Joseph E. Carberry, in command of the School, is arranging to obtain a camera so devised that by pulling a trigger the pilot can photograph a machine which he is pursuing, simulating the action of a machine gun in actual warfare. By taking a series of pictures of the pursued aeroplane, it hoped that the pilot of the pursuing machine will gain actual experience in the manoeuvering of his aeroplane and obtain visible evidence of his success in these manoeuvers. The camera will be mounted in the same position as a machine gun would be and it is assumed that if a pilot is successful in shooting a hostile machine with a camera, he would be successful, in warfare, in doing it with a gun.

Later the students will be given a chance to operate machine guns which will be carried by pursuit plans having a maximum speed of 105 miles an hour. Eight of these have been ordered by the Government and six will be shipped to the field at Mineola.

A most interesting experiment at the field was one made a few days ago, when rockets were attached to the struts of several machines. The rockets were exploded by an electrical device and were intended to be effective in destroying war balloons. Captain Carberry has made application to the Army balloon station at Omaha for balloons with which to experiment in this way.

Bomb dropping to test accuracy is also taken up. To afford better protection to the hangars, flood lights have been set up on towers near the front of the hangars.

The field is under armed guards, no one not having a pass being admitted at any time.

A dozen or so of the aviators who were trained to fly by private contributions last year and have tests have applied for admission in the Aerial Reserve Corps, and have been admitted. These include Captain R. C. Bolling, Philip A. Carroll, Lieut. James E. Miller, Cord Meyer, Charles Reed, Seth Low, Jr., Frederick Blakeman, H. H. Salmon, Jr., Edward Post, H. B. Baker. Charles Reed has also passed the Junior Military Aviators' tests.

As these men are well advanced, the next step should be allowing them to train with pursuit machines, but as there are not any available, there have been placed two training machines for them to use on Governor's Island. As in case of trouble they would serve in the Squadrons having charge of the aerial defenses of the city, and the attacking forces would have aeroplanes capable of a speed of close to 120 miles an hour, it is positively necessary that they be given fast machines for training, and that they be taught aerial gunnery, wireless, bomb dropping, aerial photography and spotting of artillery fire. And their number should be increased as fast as possible until we have at least one hundred well trained military aviators and as many military balloon operators for the defenses of New York.

Army and Navy News

First Lieut. Clearton H. Reynolds, Aviation Section, S.O.R.C., is assigned to active duty at Mineola, Long Island, N. Y. (Feb. 21, War D.)

The following promotions and appointments, Aviation Section of the Signal Corps, are announced: To be sergeants first class—Sergts. Earl F. White, James S. Krull, Robert P. Grey, Charles R. Forrest, Stanley V. Coyle, William R. Morrison, Richard H. Greyfield, George F. Faircloth, Albert A. Fletcher, Charles S. Lee, Walter S. Smith, Bert Hart, Harley A. Moore, Joseph Castillo, Newt Frey, Wilburn C. Dodd, Arnold Ruef, Jacob F. Kuhn, Henry Daum, John W. Frewer and James Devitt, to date Feb. 16, 1917, and Pvt. George B. C. Kuster, to date Jan. 22, 1917.

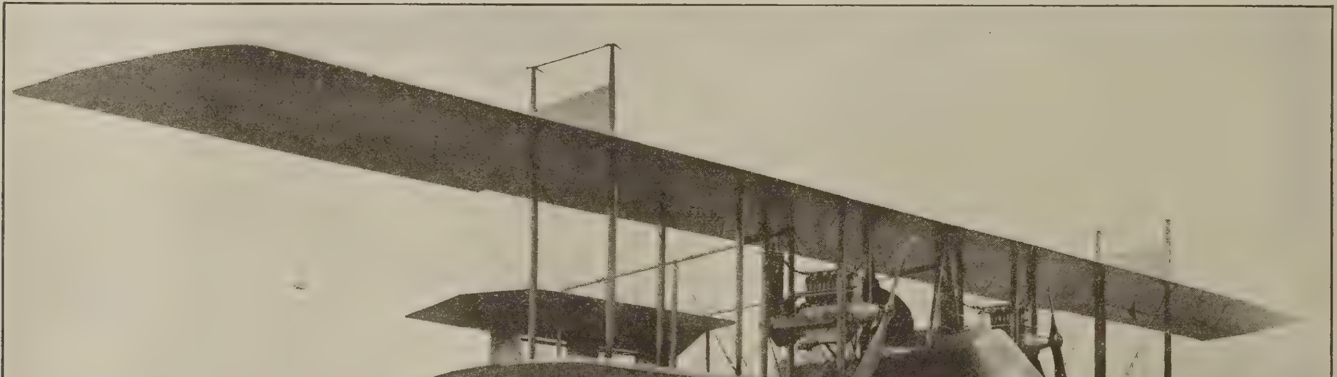
Sergt. James R. Graham, of the Signal Enlistment Reserve Corps, is assigned to active duty in the Aviation Section, Signal Enlisted Reserve Corps, with station at the Curtiss Aviation School, Miami, Fla., Feb. 24, 1917. (Feb. 24, War D.)

Sergt. Samuel B. Eckert, Signal Enlistment Reserve Corps, Fort Monroe, Va., to active duty in the Aviation Section, Signal E.R.C., with station at the Curtiss Aviation School, Newport News, Va., Feb. 26, 1917. (Feb. 26, War D.)

N. Y. AERO CONSTRUCTION CO'S SEAPLANE

The hydroaeroplane recently completed and tested by the N. Y. Aero Construction Co. has a supporting surface of 820 sq. ft., twin Aeromarine motors, 100 h.p. each, and twin pontoons, weighs 2,700 lbs. and has room for a useful load of 1,700 lbs. Its maximum speed is 85 miles per hour, minimum, 43 miles per hour, and has a flying radius of nine hours. Due to advanced type of pontoons and other features embodied in the plane, it rose from the water on test within fifty feet, Aviator W. Leonard Bonney flying. The pontoons can be replaced by land rigging.

The plane was designed and constructed under the supervision of Mr. Warren S. Eaton, who is a pioneer in the aviation business, having designed and constructed planes for the Glenn L. Martin Co. of Los Angeles. He also designed and built four of the most efficient planes for Lincoln Beachey, which had their demonstration before people in the West.



COURSE OF INSTRUCTION FOR STUDENT NAVAL AIRMEN

AERIAL AGE is this week able to present to its readers an outline of the course of instruction for student airmen at the Pensacola, Florida, station.

Upon reporting to the flying school students are divided into sections, each section spending about twelve weeks on shop instruction and about a month on the beach with aeroplanes. When the marks in all shops and on the beach are satisfactory, the student is qualified as an airman.

The terms of the course are as follows:

The time spent in the various departments is as follows:

Erecting Shop............	3 weeks	Multiple 3
Motor Erecting Shop......	3 "	" 2
Carburetors & Magnetos....	1 week	" 1

2. Upon becoming qualified airman the required number of Student Quartermasters will be selected, the rest of the qualified airmen will undergo a course of instruction for the rating of machinist (aeronautic).

3. Student Quartermaster will receive instructions in flying and will undergo a theoretical course of instruction in aeronautics.

4. The course of instruction for machinist's (aeronautic) will be published later.

5. Marks on all shops will be on a scale of 5. A mark of three in each and every subject is necessary to pass.

AEROPLANE ERECTION SHOP

Shop Instructor, Lieut. (j.g.) R. D. Kirkpatrick, U. S. N.

Asst. Shop Instructor, Lieut. (j.g.) M. Masek, U. S. N.

Assistant Instructors: H. E. Adams, R. L. Naford, H. J. Knapp, J. Galvin, B. Rhodes.

I.

(a) Names of all parts of aeroplanes.
(b) Kinds of material used in wings, pontoons, propellers, struts, fuselage, etc.
(c) Instruments carried in the different aeroplanes and the purpose of each.
(d) Approximate overall dimensions of the various types of aeroplanes.

II.

(a) Method of assembling
(b) Method of wiring and location of struts.
(c) Method of securing wings to fuselage in different types of aeroplanes.
(d) Method of securing pontoons to planes in different types of aeroplanes.
(e) Method of securing horizontal rudder, vertical rudder, ailerons or wing flaps, vertical fin, and stabilizer of various aeroplanes.

III.

(a) Factor of safety usually required in aeroplane construction for the use of the Navy.
(b) Kind and approximate size and strength of control wires and other wires.
(c) Describe three ways of making a wire terminal and tell which way is most efficient.
(d) The general design of various fittings used, such as wing fittings, strut fittings, ponton fittings, fuselage fittings, control surface fittings, etc.
(e) Which aeroplane used turnbuckles in their wiring and which do not. How may an aeroplane be assembled if no turnbuckles are used?
(f) At what angle are pontoons set relative to wings, and reason for same.

IV.

(a) How are propellers balanced?
(b) How are propellers secured to the various motors.
(c) How are propellers marked and what record is kept of them?
(d) How are aeroplanes marked?

V.

(a) Trace the gas loads from tank to motor in the different aeroplanes.
(b) What method is employed to fight fire in Navy tractors?
(c) Names and general description of the different methods of controlling an aeroplane in flight.
(d) What arrangement is made to control certain aeroplanes on the water?

VI.

In addition to the above general questions on construction and assembly of aircraft, the knowledge of the following with reference to experiments and tests is required:—

(a) Method of testing material with Tinis Olsen Testing Machine and general description of same.
(b) Method of testing material for compression, and description of machine for same.
(c) Method of stretching wire, including description of macine and reason for stretching.
(d) Method of bending wire description of wire bending machine.
(e) Method of finding center of gravity of an aeroplane.

MOTOR ERECTING SHOP

Shop Instructor, Lieut. (j.g.) E. H. McKitterick, U. S. N.

Asst. Shop Instructor, Lieut. (j.g.) L. L. Rabbitt, U. S. N.

Assistant Instructors: W. E. McCaughtry, A. A. Golay, G. Fahy, H. Hansen, S. D. Thornton.

The following motors will be studied: Curtiss OXX 2, Hall-Scott, Thomas and Sturtevant.

I.

(a) Lecture on the principles of the internal combustion engine or gasoline motor.
1. Definition of a motor.
2. Explanation of the term cycle.
3. Two and four cycle motors.

(b) Practical explanation of motor.
1. Function of different parts.
2. General nomenclature.

II.

a) Disassembling of a motor.
1. Steps in disassembling.
2. Detailed nomenclature.
3. Material used in different parts and why?
4. Forms and size of bolts, parts, etc. and reason for same; locking devices and reasons for same.
5. Notes on any worn, cracked, bent, twisted or found weakened part and the reason for this condition and how to correct.

III.

(a) Overhaul of motors.
1. Cleaning of parts.
2. Tests for alignment, as far as cam-shaft, main shaft, face plates, and gear balance.
3. Trace oiling and water systems.
4. Thorough examination of all parts for flaws or worn places as scorings in cylinders, etc.

IV.

(a) Assembling of motor.
1. Spotting in main-shaft.
2. Fitting Cam-shaft.
3. Reaming out wrist-pin bearings.
4. Test main-shaft for balance.
5. Grinding in of valves and testing same.
6. Testing valve springs, exhaust and intake.
7. Fitting thrust block.
8. General assemblage.

(b) Timing of motor and valve setting.
1. Method of adjusting valve clearance and reason for clearances.
2. Method of timing magneto and reasons for advance.

(c) Final adjustments and connections before going to test stand.

V.

(a) Test stand.
1. Connecting up motor.
2. Securing propeller.
3. Data required for motor tests and the requirements for an aeronautic motor.

(b) Motor troubles.
1. Causes.
2. Results.
3. Connections.

(c) Care and upkeep.

CARBURETORS AND MAGNETOS

Shop Instructor, Lieut. (j.g.) H. B. Cecil, U. S. N.

Assist. Shop Instructor, Lieut. (j.g.) C. T. Hull, U. S. N.

Assistant Instructors, S. D. Thornton, R. T. Cupples.

I.

(a) Carburetors.
1. Theory of the carburetor.
2. Theory of the Zenith carburetor.
3. Jets, chokes and their uses.
4. Carburetion troubles and their remedies.

II.

(a) Magnetos.
1. Electrical principles of the magneto.
2. High and low tension magnetos.
3. Dixie principle.
4. Bosch principle.
5. The construction of both magnetos, and the difference between them.
6. Distributor, its construction and use.
7. Magneto circuit.
8. Spark plugs.
9. Coils.
10. Timing and firing order.
11. Magneto troubles and remedies.

JOINER, COPPER AND FABRIC SHOPS

Shop Instructor, Lieut. (j.g.) C. P. Mason, U. S. N.

I.

Joiner Shop.
(a) Nomenclature of parts.
(b) Wings, fins, struts and stabilizers.
1. Contsruction of ribs.
2. Longitudinals.
3. Spars.

(c) Floats.
1. Outside: keel, steps.
2. Inside: bulkheads, frames, supports.
3. Drains.
4. Methods of fastening to aeroplane.
5. Various types.

(*Continued on page 28*)

The Curtiss Seaplane in which Captain Evans of the Aeronautic Station at Pensacola, looped-the-loop on February 14, and in which Lieut. McDonald, U. S. N., duplicated the feat the following day. In the photograph are seen various members of the State Militia detailed for instruction at Pensacola.

MINEOLA AIRMEN HAVE AERIAL MANOEUVRES

Garden City, March 9—Flying under conditions hitherto considered unconquerable, the student aviators of the Government school at Hempstead Plains, L. I., made a remarkable demonstration of their ability to do war work yesterday. Their progress showed that American aviation has taken a long stride forward.

These aviators had to buck against the uncomfortable handicap of nearly a foot of snow on the ground to make rising and landing perilous, yet they met the new conditions in a way that the regular army officers in command admitted they had not expected to see. Two minor accidents occurred. In one a machine turned a somersault just as it left the field when it brushed into a bank of snow. In the other a machine turned over when it ran into an embankment on landing.

That neither accident was due to carelessness was shown by the fact that one mishap came to Capt. Joseph E. Carberry, commandant of the school, and the other to Capt. A. W. Briggs of the British Royal Flying Corps, who came to this country on leave of absence after a long war experience. In both accidents the damage was confined entirely to a broken propeller of the machine.

The work yesterday was not an exhibition, for the school is under military control and the general public is not allowed inside the gates. It was a manœuvre pure and simple, its purpose being partly to test the men in mimic war and partly to determine the possibilities of an aerial attack on the field, on nearby fortifications and even on New York. Similar tests are to be held every few days during the coming year.

Capt. Carberry and the other officers and instructors at the school had been planning the manœuvre for several weeks, but each time it was scheduled rain or heavy fog came to make practical reconnaissance impossible. On Tuesday it was decided to go ahead yesterday regardless of anything but the necessity for a clear sky. The heavy snowstorm threatened to stop the plans, but a crew of mechanics and helpers were at work all Tuesday and yesterday morning shovelling a runway about twenty-five feet wide and 150 yards long near the hangars, from which it was expected the machines could rise.

Everything seemed to go wrong at the start yesterday. In the first place word was sent that a squadron of aeroplanes from Governor's Island, which had been expected to act as the enemy air fleet, would not take part because they could not rise from the snow at their station. It was then decided to use three of the fast L. W. F. machines at the school for this purpose.

So bad was the condition under foot that it was found impossible to get a heavy automobile through the snow to the L. W. F. hangars on the opposite side of the big field from headquarters to carry the pilots to their machines. It was necessary to take them over in aeroplanes. For the first time in history, perhaps, an air machine was called upon to do a job of transportation that a land truck could not handle.

By 3 o'clock things were ready. There are thirty-five machines now at the school, but for lack of sufficiently experienced pilots only eighteen could be used in the manœuvres. All these, however, were out in front of their hangars in the snow, their engines purring like huge cats as they were warmed up for their work.

Soon after a few machines began to go up to "feel out the air." One of the first of them was the Curtiss machine, No. 171, with Capt. Briggs as pilot and Bert Acosta, the former Curtiss instructor, as observer. Capt. Briggs rolled up to the shovelled pathway and then swept along it for the takeoff.

He had gone about 100 yards and was just lifting from the ground when a sudden gust of wind hurled his machine into a mound of snow alongside. The tip of the lower plane caught in the embankment. The biplane, stopped unexpectedly while going at express train speed, somersaulted. Its tail rose in the air and circled down until the machine was bottom up, the two men underneath.

A crowd of students, instructors and mechanics ran to the spot, a squad of them bearing stretchers. By the time they got there Capt. Briggs and Acosta had crawled out from the tangle and were laughingly shaking hands over their escape. The machine suffered a splintered propeller but nothing more.

Thereafter the pilots avoided the shovelled pathway. One of the more daring first discovered that the crust of the snow had softened to such an extent that he could get off right from the field. Thereafter they all did it, although every machine had to be helped out by perspiring machinists until it was ready to start away.

The machines landed on the snow, too. Not one had ever tried it before, and it took unusual skill. It was impossible to volplane down and roll along for a hundred yards in the usual way. The machine had to "pancake" down flat and come to an immediate rest or its momentum would turn it into a nose dive as it struck the snow.

The proceedings were held up for some time by the fact that the enemy could not get up. At last they got away. Leonard Bonney, formerly head of Carranza's Mexican aviation corps and now a Government instructor, had one machine. The two others were piloted by A. Livingston Allan and Harold Blakeley. They had received secret instructions to fly over Oyster Bay and then return by three separate routes, evading the protecting squadron.

After a long period of waiting Capt. Carberry decided to fly over to the L. W. F. hangars himself and see what was wrong. He found the trio ready to start, and to signal the joyous fact he turned a loop the loop in the air on his way home. Unfortunately, however, he landed in a snow embankment and did another loop on the ground that turned his machine upside down with a broken propeller. He himself was not scratched.

As soon as word came that the enemy machines were on their way fifteen protecting biplanes went up. Lined up in single file, one behind the other, they began rising from the snow. At last all were in the air and a few minutes later had reached altitudes ranging from 1,000 feet to 6,800 feet. At the latter height they were invisible and the hum of their motors could not be heard.

It was nearly 6 o'clock before the three enemy planes came home. Allan, flying at the extreme height of 9,600 feet, had come in over Hicksville. He had seen a number of the home air fleet, but came through with only a few of them having been able to distinguish him by the black and white stripes painted on his fuselage. Bonney, flying at 8,200 feet, passed over the cordon and so did Blakeley, who kept lower.

The three biplanes were "spotted" by a number of the pilots, who were instructed to turn in reports in writing this morning. It appeared that it would have been impossible for an aerial enemy to come in undiscovered on a clear day, but the manœuvre demonstrated the need of fast pursuit planes for defence purposes. The pilots admitted that they could never have overtaken the invading machines, although the L. W. F.'s have a speed of but ninety-four miles an hour.

Six of these fast scouts are now being bought for the school for advanced work and will be on hand in a week or so. They will be two Curtiss triplanes, two Thomas battle biplanes and two Sturtevant biplanes. A Curtiss twin motored R-2 biplane is also being assembled in the hangars.

There are now thirty men under instruction at the school and twenty applications a day are being received. Capt. Carberry expects by May 15 to have fifty men in training. The course will take three months, and each month a new class will be started, so that by July there will be 150 students at the field. The school expects to turn out 480 experienced civilian pilots a year capable of military service.

The men who piloted the home squadron yesterday were Capt. Briggs, Lieuts. Ivan P. Wheaton and A. J. Coyle; Sergt. L. V. Smith; Corporals W. P. Willetts, H. H. Salmon and Robert M. Olyphant; Privates Daniel Morse, H. F. Wehrle, Charles Post, Havilock Simon and W. H. Watkins, and Instructors P. C. Millman, Filip Bjorklund and N. J. Norton.

Some of the Army instructors who took part in the air manoeuvres.

THE LEWIS AUTOMATIC MACHINE GUN

THE Lewis machine gun is an air-cooled gas-operated, magazine-fed arm, weighing 26 pounds. It is entirely free from external accessories for cooling, feeding or any other purposes as an automatic pistol. And, except for the difference in size and weight is just as mobile—as quick to get into action, capable of operating in any position, of firing straight up or straight down, or of being fired when turned on either side or upside down.

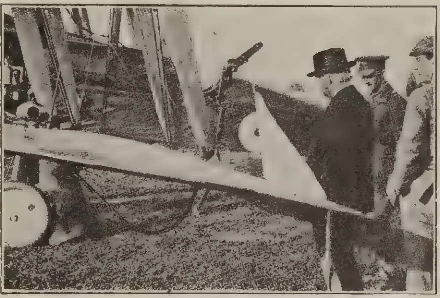
The speed of getting into action and the ability to function automatically in any position are due to the use of detachable drum-shaped rotating magazines. Each magazine holds 47 or 97 cartridges. When a magazine is latched on the magazine-post it temporarily becomes a part of the gun, requiring no further attention until empty, when it is snatched off and another snapped on as quickly as an empty magazine is dropped out of an automatic pistol and a loaded one inserted.

Cooling in the Lewis Gun is by air, but it is an active, positive process. The gun cools itself so that a perfectly safe temperature is maintained even during the most extended periods of automatic fire. The cooling means is incorporated in the design of the gun, and makes no demand on the attention of the operator.

This is accomplished by entirely surrounding the barrel with an aluminum radiator having thick high radial fins extending its entire length. Aluminum is especially suitable for this purpose, not only because of its lightness, but on account of its high thermal conductivity —the speed with which it conducts heat from the hot barrel to the surrounding air. The high fins of the radiator present an enormous radiating surface to the air, but cooling by simple radiation from all this exposed surface is not relied on. Provision is made for ensuring a very strong current of air along the radiating surfaces of the fins from breech to muzzle.

For this purpose the radiator is enclosed in a thin sheet steel casing, open at both ends, and extending well beyond the muzzle of the barrel. The muzzle-blast from firing, properly directed by the barrel-mouthpiece to produce the greatest suction-pump effect on the radiator casing at the muzzle, pulls a column of fresh air through the grooves between the radiator fins each time a shot is fired. So that during automatic fire a steady column of air is being pulled through the radiator at high velocity, carrying off the heat transmitted from the barrel.

The Lewis gun mounted on the Atlantic Aircraft Co.'s trim motored battleplane.



Hon. H. H. Asquith examining gun on British aeroplane.

Power to operate the action is obtained by taking powder-gas from a small port in the barrel near the muzzle into a cylinder under the barrel, where it drives rearward a piston at the front end of the operating rod. This opens the action.

By the opening stroke the breech bolt is unlocked and withdrawn, the fired shell extracted and ejected, a cartridge is carried by the feed-arm from the magazine into feeding position in the receiver, the magazine is rotated and locked, and the mainspring is wound up.

Also, if the trigger is not held back, the sear will engage with its notch in the operating rod, and the gun will remain in the "ready to feed" position with action open and chamber empty.

But if the trigger has been held back, the closing stroke of the action instantly follows the opening stroke. Otherwise, it does not occur until pressure is again applied to the trigger, drawing the sear out of engagament with its notch in the operating rod. The operation of the gun is continuous as long as there are cartridges in the magazine.

Power for the closing stroke is supplied by the mainspring, which rotates the gear and drives the operating rod forward by means of teeth on the surface of the gear wheel meshed with teether under the operating rod, just reversing the motion by which the spring was wound up by the opening stroke. With this closing stroke the breech bolt drives the cartridge in the receiver ahead of it into the chamber, the bolt is cammed around the lock, the extractors taking hold of the rim of the cartridge, the feed arm is returned to its former position at the right, and finally at the end of the stroke the striker hits the primer of the cartridge and fires it. And as soon as the bullet gets beyond the gas port in the barrel the opening stroke commences.

It will be noticed that when pressure on the trigger is relaxed and the gun stops firing it is left with the action open and the chamber empty. This not only still further facilitates cooling, but prevents the unintentional firing of a cartridge in the chamber by heat from the barrel. In other machine guns when firing is stopped before the gun is empty, it will leave a loaded cartridge in the barrel. Unless it is instantly removed, the heat of the barrel will in a few seconds fire this cartridge.

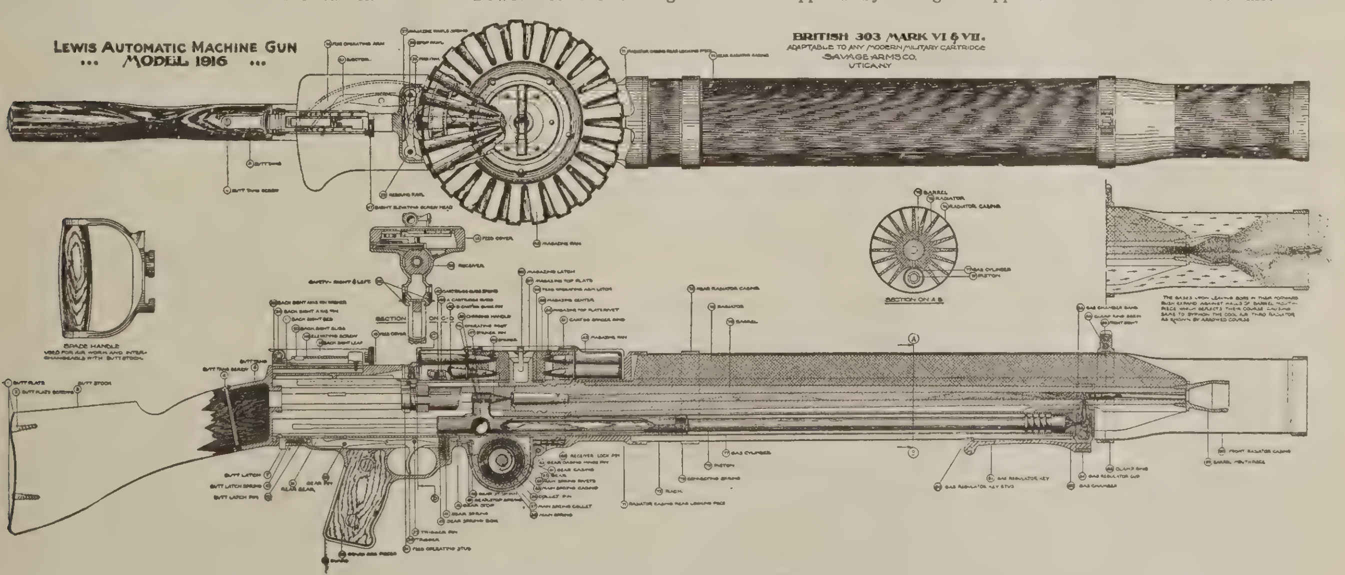
The action of the Lewis is especially attractive to a rifleman. The gun may be entirely dismounted without the use of any tool except a small spanner. The breech bolt rotates to lock and unlock and has four large, substantial locking lugs. This rigid and secure form of breech closure prevents the increased head-space and consequent breakage of shells characteristic of machine gun actions locked by toggle-joints or by locking blocks, and this with modern military cartridges of high concentration, is a matter of vital importance.

A feature of great practical value is the ability of the Lewis to fire single shots on the same line of sight that is used for automatic fire. With other machine guns it is a matter of common knowledge that automatic fire and semi-automatic fire requires different sight adjustments due to the difference in barrel vibration and consequently in flip. In the Lewis the contract and support of the radiator limits and breaks up barrel vibrations, and as a result flip is reduced to a point where it is negligible.

Another interesting feature is that the pull of the powder gases exerted on the front end of the radiator casing counteracts the recoil so effectively that it becomes merely a moderate and steady rearward push. Consequently the gun may be fired offhand from the shoulder if desired, and the necessity of a heavy tripod to secure permanence in alignment during automatic fire is practically obviated. For fixed positions on the defensive some form of tripod is usual but for offensive where mobilty is desired, the 3½ pound field mount has proven perfectly adequate.

It is obvious then that the Lewis may be used with tripods or mountings of any design, and when so mounted the horizontal or vertical angle at which the gun may be fired is restricted solely by the limitations of the tripod.

With the many features described above the Lewis Gun has shown a versatility and sureness of action that makes it equally effective on either the rigid base in land actions or the undulating, fragile supports on water or in the air.



Section diagrams of the Lewis automatic machine gun.

THE GERMAN AEROPLANE ENGINE TRIALS

A Detailed Description of the Equipment and Proceedings

ALTHOUGH these trials were held as long ago as 1913, the following is the first really complete description of the somewhat original testing plant employed. Effort will be made to describe in some detail the results obtained and the conclusions reached by the judges. When it is remembered that prizes to the extent of over $30,000 were awarded, it will be clear that the competition was one of some importance. The notes to follow are based upon a detailed account of the plant, and a complete report of the proceedings, so the information that will be given should be of some value and considerable interest to the many firms who are manufacturing aero engines and also to designers. At the time that the trials were held, few British firms were engaged in the construction of engine for aircraft, and such reports as did appear in our technical press were very brief.

Most readers will be surprised to learn that forty-four actual entries were received, together with twenty-four reserve engines, which could be used if the engine under test suffered from some misfortune not coming within the rules. The result was that over sixty engines had to be tested within a period of ten weeks.

As stated, most of the plant was original, and, further, it had to be adaptable for use with all the different types of competing engines, including rotaries, as well as air and water-cooled stationary motors. Although not specifically stated at the time, it is quite obvious now that one of the chief objects of the competition was to stimulate the production of aero engines for war purposes, and therefore consideration was given to manufacturing points, and as well as to the efficiency of the engines or their suitability for aviation work. However, the chief point to receive consideration on the part of the judges was the total weight of the engine and fuel, etc., for a seven hours' run in relation to the b.h.p.

To arrive at a proper result, it was realized that it would be useless to ascertain the b.h.p. by the usual brake methods, because the propeller, normally in use, serves as a flywheel, and yet it would not be correct to substitute for it a flywheel. It was not, however, considered practical to obtain the required figures from the thrust developed by a propeller supplied with the engine, as there were many different types of propeller available, and such a test would have resulted in the production of a number of freak air screws just as the Prince Henry motor car trials produced freak cars.

It was finally decided to fit to each engine a standard propeller designed for the power and type of engine under test, and to arrive at the horsepower by ascertaining the torque reaction. For this purpose the engine was mounted upon a cradle which could rock, and the rocking tendency, or torque reaction, was measured. From the figures so obtained the power was ascertained.

In the case of rotary engines some allowance had to be made for the churning of the air by the engine cylinders, because this in itself creates a torque reaction which obviously is of no value when calculating horsepower. It was decided not to take into consideration the head resistance of the engine, as this point was largely affected by the method of mounting the engine on the aeroplane, and, although one engine might be better than another in this respect, it is clear that this point had to be ignored. Unfortunately, for some reasons, the water-cooled engines were not tested with their own radiators, because here again was an opening for the production of a "freak," and, after all, the radiator is not so intimately connected with the engine as is the carbureter or the ignition apparatus. Furthermore, the radiator is not, as a rule, made by the engine manufacturer, but is the product of a separate specialist, and therefore in a test of this kind it was decided not to handicap the engine maker for a possible fault on the part of the radiator manufacturer. It may be well to mention that the weight of the radiator should be added to the weight of the engine in order to arrive at the mass of the whole plant, and that it was found the radiator weight ought to be estimated on a basis of .389 pounds per 1,000 b.t.u. This figure should be used to ascertain the total plant weight. This figure includes water tanks and connecting pipes. During the test the entering water was maintained at 70° C.

A point which will strike the casual reader is the complication of the test plant, and one may well inquire why simpler plants could not be used, such as those employed nowadays by every maker of aeroplane engines. It must therefore be made clear that there is a big difference between these trials, which were competitive, and the ordinary tests made by a manufacturer. The necessity of employing a propeller of some kind has already been mentioned, and the presence of this prevented the power being ascertaind by electrical or other means. The chief point is, therefore, that to compare one engine with another it was essential to make the conditions of the trial approach as closely as possible to those which would obtain when the engines are in normal use. The manufacturer, however, merely wishes to know that each engine will produce certain figures on his testing instruments. If he wishes to compare one engine with another, his test must be made very much finer, and if he deems it essential to fit a propeller, and not a flywheel, during his tests, then he must employ some such plant as that which was used in these trials. Another point was that one of the aims of the trials was to ascertain the reliability of the engines under flying conditions, from which it will be clear that the use of a propeller was essential. Therefore, each competitor had to send in his engine fitted with a propeller, which was calibrated and measured up during the trials.

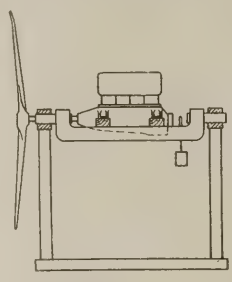


Fig. 1

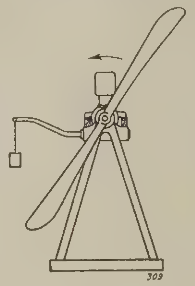

Fig. 2

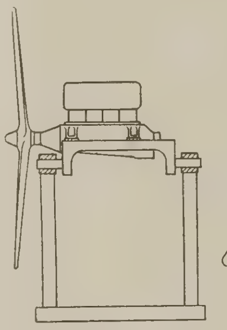

Fig. 3

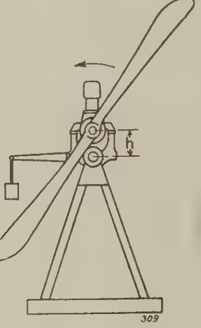

Fig. 4

Briefly, the testing plant comprised a cradle upon which the engine was mounted and which could rock, tending under the torque reaction to turn in a direction opposite to the propeller rotation. This tendency was balanced by weights placed upon a scale pan, and, by means of the weights or by using a pressure gauge acted upon by the balance beam, the output of the engine could be ascertained.

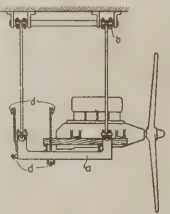

Fig. 5

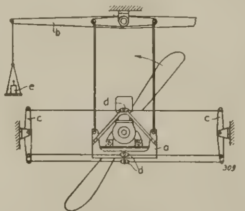

Fig. 6

To gauge the propeller of each engine—which was necessary, as they and their speed of revolution varied—it was essential to employ a special electric motor with a long shaft, which normally was disconnected from the propeller. For this test, the propeller could be disconnected from the crankshaft and fitted to the end of the motor shaft and the electric motor set running. This instrument was of a special type, as the power output could instantly be measured by ascertaining the reaction of the housing, which was quicker and more accurate than measuring the current consumption and making allowances for loss of efficiency.

Another condition of the trials was that the motor should be run under test in tilted as well as horizontal positions, and therefore the cradle was suspended so that it could be inclined, as shown in Fig. 5, through an angle of 25°. By this means it was possible to test the engine under conditions of ascent and descent. It was also essential that the engine should be capable of running slowly and of rapid acceleration both in a horizontal and an inclined position. It was a further condition that the engine should be tested for its flexibility up to its maximum speed.

In the case of air-cooled engines a special fan was provided to supply an air draught, which is shown at *n* in Fig. 14. This was mounted upon a sleeve through which passed shaft *l*, and it was driven through a belt from a second electric motor *m*.

It was realized that, in spite of the somewhat elaborate test plant, the exact conditions could not be reproduced, because on an aeroplane the engine is traveling through the air, and it is almost impossible to reproduce this feature in a test shop. Further, a test bench, even with a rocking cradle such as that used in these tests, is obviously more rigid than an aeroplane fuselage, and therefore vibration effects were not noticeable during the trials. It had been suggested that the engine be tested on a whirling table comprising a long arm rotating about a center, so that the trial could be made with the engine in motion, but this was deemed wholly impracticable owing to the very high speed of revolution which would be necessary to approximate to flying speeds; and, again, because the engine would continually be traveling in its own wake, and the air would be too much disturbed by it and by the apparatus upon which it was mounted. If it were essential that the engine should be tested traveling through the air, it would be ridiculous to carry out a trial in which the engine was continuously moving through air which it has passed through. Unfortunately, aerial disturbances cannot be seen, and therefore there is a tendency to use whirling tables and so forth for tests.

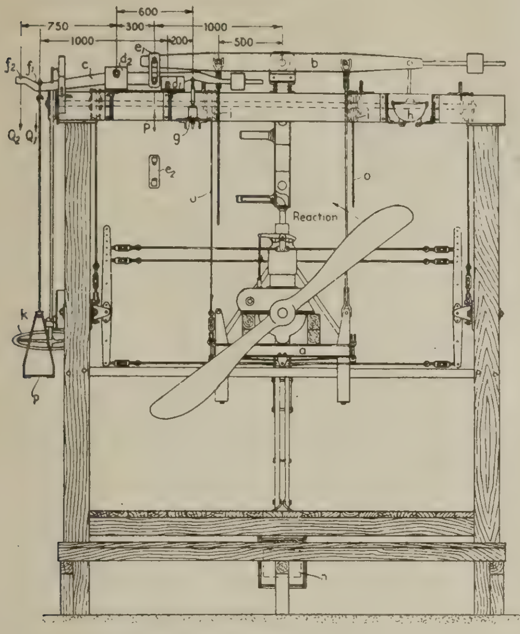
It is suggested that results obtained in this way are of little or no use. In testing hull forms in ship designs, it is not the custom to use circular movements, although in such a case it is possible to eliminate disturbances due to the arm by supporting this out of the water, but there still remains the wake behind the model being tested, which creates a disturbance of the water lasting for a considerable time. For the same reason it was considered quite impossible to employ any reasonable form of moving test bench in these trials, but the engines were run in air currents of various directions.

The Test Plant

As will be gathered from the introductory notes, the major portion of the test plant had to be specially provided, as there was nothing in use sufficiently elaborate to test engines according to the conditions. At the Zeppelin works at Friedrichshaven the Maybach engines are tested on a swivelling cradle, which is illustrated in Figs. 1 and 2, and although this bench can be used satisfactorily for these particular engines, it could not be employed for the competing engines.

It will be noticed that the crankshaft in Fig. 1 projects very considerably to the left and that the propeller is mounted beyond the trunnion. This correct coaxial arrangement is quite practicable in the case of airship engines, because the crankshaft normally projects in this way, being connected by gearing with the propellers; but with aeroplane engines there is little or no crankshaft projection, and the propeller is mounted very close up to the front of the crankcase. To use a rocking cradle of this kind would mean providing special extensions for the crankshafts of all the engines, and this in turn would introduce complications due to whip and vibration, which would probably necessitate special bearings and other constructional features. As the idea of these trials was to test standard engines, it was obvious that the judges could not reasonably expect manufacturers to make special provision to suit their testing plant.

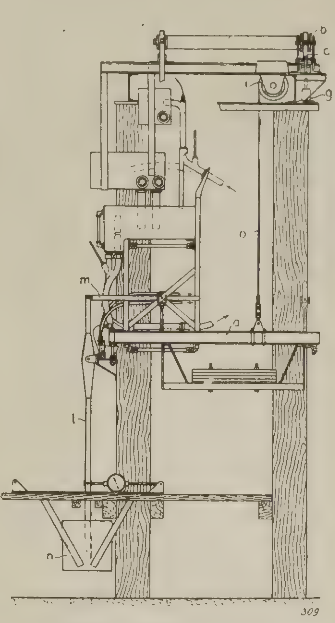
In Figs. 3 and 4 is shown an alternative suggestion, in which the trunnion for the cradle is eccentric to the axis of the crankshaft, the eccentricity being indicated by the height *h*. This arrangement is sometimes used, but it was discarded, as it introduces inaccuracy owing to the fact that the resistance to the travel of a propeller blade may be different during the upper half of the revolution from what it is during the lower half, in consequence of the interference created by the legs of the stand. This type of



Right-hand propeller.

$$P = Q_1 \frac{1000}{100} = 10\ Q_1$$

$$P = p\,l \frac{200}{100} = 2\,p\,l.$$



Left-hand propeller.

$$P = Q_2 \frac{750}{300} = 2{\cdot}5\ Q_2$$

$$P = p\,l \frac{600}{300} = 2\,p\,l.$$

With indicator No. 1 of piston area 10 sq. centimetres P in kilos or torque reaction in metre kilos = 20 p.
With indicator No. 2 of piston area 5 sq. centimetres P in kilos or torque reaction in metre kilos = 10 p.
With indicator No. 3 of piston area 2·5 sq. centimetres P in kilos or torque reaction in metre kilos = 5 p.
P and Q in kilogrammes.
p in kilogrammes per square centimetre.
P acts upon a beam l of a length of one metre. Therefore the torque reaction in metre kilogrammes is equal to P in kilogrammes.

Fig. 7

Fig. 8

rocking cradle incidentally is, or was, used by the Automobile Club of France in connection with certain aerial engine competitions.

A point to be noted in connection with these trials is the great care exercised in selecting and constructing the testing plant to avoid any possibility of error.

The authorities finally arrived at a type of rocking cradle that appeared to comply with all requirements, and this is illustrated separately in Figs. 5 and 6, and in position in the testing shop in Figs. 7 and 8. The cradle *a* upon which the engine was mounted was slung by a pair of suspension rods from horizontal rockers so arranged that the cradle could rock round the crankshaft axis. It will be seen from Fig. 5 that this arrangement did not interfere in any way with the position of the propeller. In addition to oscillation about the crankshaft axis, a cradle of this kind can obviously swing (pendulum fashion) about its suspension if no provision be made to prevent it. This swivelling clearly had to be prevented, and to cope with this rockers *c* were fixed to each side of the cradle and were coupled by wires, with the points d on the cradle. Two sets of wires were used, and these were arranged at the end of the engine remote from the propeller, in order not to interfere with the engine or any of its accessories. This cradle was therefore capable of rocking about the crankshaft axis, and it could also move slightly longitudinally in order to measure the thrust of the propeller. The suspension rods were therefore universally jointed to allow of these two movements. For measuring the thrust of the propeller, or alternatively the head resistance of the engine, when the propeller was driven by the electric motor the fork *m* was pivotally connected with the cradle and was coupled to the lever *l*, the lower end of which entered a dashpot *n* (see Fig. 8). The lever was fitted with a plate working in the dashpot, and was coupled to a spring balance or some other form of indicator, which is also clearly visible in Fig. 8.

To tilt the engine in order to make tests under conditions similar to those which exist when rising or descending rapidly, the front suspension rods were removed and the cradle supported by the two cables *o*, which pass round the pulleys *i* (Figs. 7 and 8). These pulleys were fixed on a shaft that could be rotated from a hand wheel *k* through worm and worm wheel gearing, so that by rotating this hand wheel the engine could be tilted through an angle of 10° above the horizontal and 15° below. The rockers and cross connections employed to prevent swinging of the cradle had to allow this tilting movement, and also had to be flexibly or universally mounted. The front pair were suspended by similar cables to follow the tilting movement.

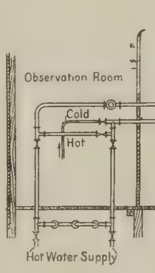


Fig. 9

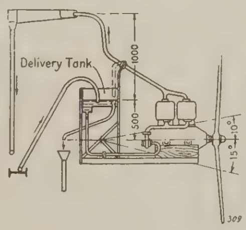

Fig. 10

The method adopted for indicating the torque reaction is shown in Figs. 7 and 8. The suspension rods are slung from a beam *b*, which rocks parallel with the cradle; this beam is interconnected with the second beam *c*, and upon the end of this are slung, from the points f_1, f_2, a pan *p* carrying weights. At *g* is a pressure indicator with an area of piston measuring 10, 5, or 2.5 square centimeters.

If Fig. 14 be examined, it will be seen that in one corner of the test shop is an observation room. In this room were stationed observers, who had before them rows of recording and gauging devices, one of which was connected with the indicator *g* (see Figs. 7 and 8). Where possible every indicating device was duplicated, so that the observers could take readings in comparative comfort, cut off from the noise of the engine, whilst on the test bench were alternative indicators, by means of which the readings in the observation room could be checked. In the opposite corner to the test room was a visitors' room, to which the manufacturer of the engine had access, and his engineers could make private observations.

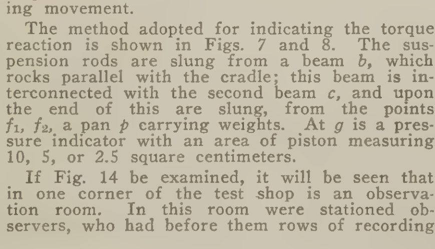

Fig. 11

Returning to Fig. 7, it should be noted that the beam and balancing mechanism there shown was designed so that it could be used both with right or left-hand engines by merely interchanging the knife edge supports d_1 and d_2 and by altering the connection e_1 and e_2 between the two beams. In the one case the connection was in tension, and in the other case it would be in compression. The apparatus was designed to work in both directions with only a small amount of alteration and without affecting the scale of the recording instruments.

Behind the cradle there is a cross beam with stops, which limit the rocking of the cradle; the cross beam also serves to carry petrol and oil piping.

The water tank is carried on the cradle (see Fig. 10). It was continuously fed with water from the mains, and there was an overflow pipe so placed that there was always a water head of half a meter above the crankshaft axis. At low speeds the pumps on most of the engines were not powerful enough to force the water up to the proper high level tank, and therefore the lower tank was used, and the water was delivered to this through the pipe shown in dotted lines. During long tests at high speeds the upper outlet pipe was raised, giving the stipulated head of water. As the water pipes and the tank on the cradle were capable of rocking, special provision had to be made when connecting up these pipes with the rigid tanks, etc.

As the trials took place during the coldest winter months, it was necessary to heat the observers' room, and for this purpose hot water from the engine was circulated through the observation room, and it was also possible to supply hot water from a distant source to maintain the temperature of the water entering the jacket at 70° C. It will be seen from Fig. 9 that various control devices for this purpose were provided in the observers' room. The hot water leaving the engine, as it flowed through the observers' room, was measured and its temperature recorded. Its temperature was then reduced to 70° C. and then returned to the engine.

The fuel supply and measuring apparatus is shown in Fig. 11. The petrol tank *a* was mounted upon a scale, under cover, outside the test shop. The tank and its contents weighed about 400 kilogrammes, and connected with the beam of the scale an electric indicator was arranged in the observation room, which showed each time the beam passed the horizontal. The weights in the scale pan were of 500 grammes each, and after each signal by the indicator one was removed and the time noted before the next signal was made by the indicator. In this the time taken to consume each five kilos of fuel was recorded.

The petrol was supplied to the carbureter through a filter tank *f*, pressure (equivalent to a head of two meters above the crankshaft) being supplied to the tank *a* from a cylinder *c* of nitrogen, a branch communicating with a mercury pot *d* which served as a safety valve. The fuel was also supplied to a graduated glass chamber e, adapted to hold exactly one liter. This one-liter flask was used during short running tests, and also was employed by the engine makers when tuning up their engines prior to the competition. When the one-liter chamber *e* was employed, the two-meter head of fuel was maintained by closing the supply cock *b*, while the vent cock *i* was also closed. The nitrogen from the cylinder *c* forced its way through the standpipe *g*, maintaining the correct head of pressure. It should be mentioned that the petrol level could be seen from the observers' room.

Lubricating oil was supplied to the engine from a tank fixed on the side of the plant. This tank contained a known quantity of oil, and the loss during running was measured by subtraction.

The indicator at *g* (Fig. 7) consisted of a piston acting in a cylinder filled with oil which was connected by a pipe with a pressure recorder in the observation room, so that the observers could continuously ascertain the torque reaction. By emptying the pipe, and placing weights upon the pan hanging from the point f_1 or f_2 on the beam (see Fig. 7), the reading in the observers' room could be checked.

The engine drove a number of revolution indicators and a speed counter. The amount of cooling water was measured by a water meter, and two registering mercury distant thermometers were employed to record in the observers' room the temperature of the water entering and leaving the engine, and, furthermore, on the actual water pipes themselves were fitted thermometers so that the indications of the distant

(Continued on page 28)

THE 1916 TYPE RUMPLER BIPLANE

IT is notable that the majority of German machines captured by the French during 1916 were Rumplers, signifying that the Germans used them in large numbers and that the Rumpler factory is well organized for output. In the French technical paper, *L'Aerophile*, the latest Rumpler biplane was most completely described and illustrated by photographs and drawings, some of which we reproduce.

Herr Rumpler has paid considerable attention to detail design, both in the system of attachment of fittings, the facility of mounting and dismounting parts, and to such things as gun fittings and the comfort of the crews.

A list of general characteristics follows:

General Dimensions

Span, upper plane	12.25 metres
Span, lower plane	11 metres
Chord	1.75-1.62 metres
Wing surface	35.5 sq. metres
Gap	1.76 metres
Length over all	7.90 metres
Height over all	3.20 metres
Weight, empty	830 kgs.
Useful load	433 kgs.
Motor, Mercedes	165 h.p.

Planes

Next the fuselage the wings have an angle of incidence of 5°. The wing section tapers from the butt of the wing to the tip, and their maximum thickness is 92 mm.

Upper planes have a dihedral angle of 2°, the outer forward interplane strut being 160 mm. higher than the corresponding point on the spar at the centre of the machine. There is no stagger, the struts being vertical.

Gap between wings, 1.765 metres. Total surface of upper plane, 19.36 sq. metres. Lower plane, 16.15 sq. metres. Total plane surface approximately 35.5 sq. metres, including ailerons but not the tail plane. In plan the wings taper, the chord being 1.75 metres close to the fuselage, and tapering to 1.62 metres.

Ailerons on the upper planes are attached to subsidiary spars and not the rear main wing spars. They are operated by a lever projecting forward from their leading edges, with a slot provided in the main plane for their movement. An upward movement of the aileron is produced by the cable attached to the lever, and a downward movement by a cable attached near the trailing edge of the aileron.

Fuselage

In the forward part of the fuselage structure, steel tube is used. The motor is carried on ash engine bearers held on steel tubes, these themselves being fixed on the summit of the rear struts of the landing carriage.

The four main longerons from the nose of machine to behind the passenger's seat for a distance of 3.5 metres are of ash, wound spirally with fabric, and behind this they are made of spruce, but not wrapped, which is contrary to the custom of other German makers.

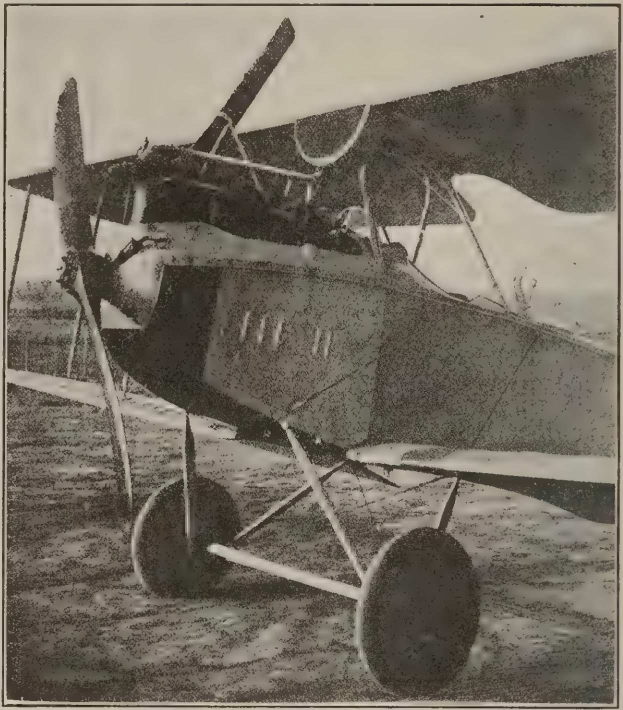
The forward ash sections of the longerons measure 40 mm. by 30 mm., and the after spruce portions, 20 by 20 mm.

The pilot's seat is in the forward cockpit, resting upon the main fuel tank. The observer-gunner is in the rear cockpit, with a seat and gun arranged to turn about on a circular track. In bombing machines release gear is provided for six bombs, with a light gun for defense only. The "destroyers" are equipped with more powerful guns.

Instruments in the forward cockpit are: revolution indicator, magneto switch, starting magneto, ignition advance and retard, pressure indicator for main tank, brake handle, pressure pumps. The compass is placed inverted under the upper right wing.

Landing Gear

Main struts of the landing chassis are of streamline steel tubing, 95 by 30 mm. section. The wheel track is 1.95 metres, and the wheels take tires 810 by 125 mm. Wheels weigh 11 kgs.



Three-quarter front view of the 1916 Rumpler.

A brake for landing is attached to the centre of the axle, operated by a cable to the forward cockpit. Its principle of action in bringing the machine to a stop after alighting is plowlike.

Tail Group

The stabilizing plane is divided, and is set at a slight angle of incidence. The span of the tail plane is 3.38 metres. The tail fin is triangular in shape, 1.12 metres long and 0.82 metres deep, the rudder standing up to a total height of 1.12 metres from the bottom of the fuselage.

The stabilizing plane has a surface of 2.25 sq. metres. Elevators, 1.70 sq. metres. Fin, 0.45 sq. metres. Rudder, 0.68 sq. metres.

The framework of the tail group is almost entirely of steel tubes. Outer edge of the tail plane is supported about half way along its length by two tubes from the lower fuselage longerons, and at the rear extremity, where it forms the hinges for the elevator flaps, it is held by two other tubes to the rudder post, which also forms the rear edge of the vertical fin.

Motor Group

The motor is a Mercedes, and test of two captured machines showed them as giving between 166 H.P. at 1400 r.p.m.,

GERMAN MILITARY BIPLANE

THE TRAINING IN MILITARY AVIATION

(Lecture by General W. S. BRANCKER, R. A., Director of British Air Organization, before the Aeronautical Society of Great Britian)

THE question of training in aviation is very controversial, and I hope that the many gentlemen here with opinions of their own will help me out at the end of the lecture by airing their opinions and freely criticising anything I say with which they do not agree. I hope to hear the Naval views, the ideas of the newly fledged pilot and pupil under instruction, and the opinions of designers and constructors. Although I have had a great deal to do with the training of pilots since I started work in the Royal Flying Corps, I do not feel very well qualified to speak on the subject, as most of my experience has been on the administration side and not in actual teaching; but I have the advantage of being able to go round visiting aerodromes and hearing a vast number of conflicting opinions. In spite of this I still feel very ignorant on the subject, and have come to only two very definite conclusions. One is that we have a very great deal to learn still regarding the best methods of training pilots, and the other is that it is almost impossible to make any two experienced aviators agree on any one point in connection with aviation.

PILOTS ARE CONSERVATIVE

Another interesting point is that the average pilot is intensely conservative and usually self-opinionated, and so thinks that the methods he is being brought up to must be the best, and hates an innovation like poison. The training of all young animals has been a subject of great interest to me from my youth up, and the training of pilots is rendered still more interesting by the fact that a mistake may mean a bad smash or death.

I think the best way to deal with the subject will be by describing to you our system of training in the days before the War, and the development of this system since the beginning of the War up to the present time. I will then discuss the various accessories necessary for the training of pilots, such as aerodromes, instructors and equipment. After this I will talk of the various methods adopted, and of possible improvements, and wind up by asking some of those present to add their quota.

TRAINING ORGANIZATION IN PEACE

Private Schools | Various sources with no training

Central Flying School

Service Squadrons | Reserve

The first diagram shown represents the organization for training which existed at the beginning of the War. Both Services depended almost entirely on the Central Flying School for the training of their pilots.

In the Army, as a rule, officers who wished to join the Royal Flying Corps called on to take the Aero Club's certificate at their own expense before being accepted. This certificate demanded a very low standard of efficiency, with the result that it was not of very much practical value, and many instructors at the Central Flying School preferred pupils who had not been instructed at a private school before. This was not altogether the fault of the private school, but rather because the gratuity which the Government allowed an officer who was accepted for the Royal Flying Corps and had taken his ticket at his own expense was not sufficiently large to ensure any very thorough training, and the standard demanded by the certificate was so low that I believe pupils often qualified after about two hours in the air.

CENTRAL FLYING SCHOOL

The Central Flying School, on the other hand, probably provided better instruction in aviation than any other similar institution in the world. The course lasted for three months, but it was always recognized that for really satisfactory results this should be extended to about six.

This was never possible, however, as the size of the school was governed by the money available and itself governed the output of pilots, and the output of pilots even in peace from this establishment was not equal to the demands of the two services. During peace, aviation was such a novel proposition that most of the training took the form of flying pure and simple. Military subjects were taught to some extent on the ground, but in the air, as was only natural, the art of handling the machine, of landing it, and of finding the way across country was all that mattered. In those days, bomb dropping, photography, wireless, and fighting in the air were scarcely mentioned. The school was divided up into several Flights, and the training was progressive through these Flights. Almost all pupils started in the Maurice Farman Flight with a period of dual control instruction. They then had a spell of solo work on the Maurice Farman, including a few short cross-country flights. From that they were moved to one of the advanced Flights and were given dual control instruction either on Avros or B. E. 2's, and so on to solo on either one of these types. A particularly promising pupil usually had the opportunity of flying two or three other types of machines before he left the school. The final test was a cross-country flight, at which a height of about 3,000 feet had to be reached, and a spiral landing with engine stopped at its conclusion. Reconnaissance height in those days was considered to be 3,500 to 4,000 feet, and it was only the exceptional pupil that reached anything higher. To sum up, the art of flying was taught as well as it possibly could be, whereas the military side of aviation, as it is understood to-day, was not really included. The school not being large enough to fill the requirements of both services, a certain proportion of officers who had taken their tickets were sent direct to squadrons for training in the early stages.

On the declaration of war all our available resources were sent straight into the field, and the only unit left intact so far as the Army was concerned was the Central Flying School, and even that was severely denuded both of instructors and of aeroplanes which were taken to bring the Service Squadrons up to their fighting strength. Then came a very lean period in England, during which very few pilots were produced, for the simple reason that neither sufficient instructional aeroplanes or instructors were available. It became necessary to formulate some sort of policy. It was obvious that if the war went on for any time we should want a great many more squadrons in the field, and the output of the Central Flying School in pilots could not possibly be sufficient for the replacement of wastage of the squadrons already in the field and the formation of the new ones. New Squadrons, Reserve Service, were therefore started at all existing stations as officers and material became available, and the question arose as to whether these existing stations should be extended to take a considerably larger number of squadrons in the future or whether new stations should be started in various parts of England.

NEW AERODROMES

The latter policy was decided on for two reasons. First, it seemed likely that the best and most economical number of pupils, given unlimited aeroplanes which could be trained on one aerodrome without undue delay and congestion, would be about 60. The number of pupils it was thought that one Reserve Squadron could properly train averaged between 20 and 30, and it was therefore considered that the ideal station should accommodate from two or three Squadrons, either Reserve or Service. The second reason was that it seemed a pity to have all one's eggs in the same basket. The wonderful English climate varies enormously in different parts of this comparatively small country, with the result that whilst the weather was hopeless in London, the Midlands might be perfect, Yorkshire might be impossible, while flying was in full progress in Scotland; it therefore seemed sound to scatter these aerodromes as much as possible. An additional advantage of this scattered disposition was that the new aerodromes would form halting places for new machines being brought down from the contractors, and that this system would also ensure, so far as possible, that all parts of the new Army training in England would see and have some knowledge of aviation. The disadvantages of this system were that the available talent in instructors was scattered instead of concentrated, and probably more instructors were required for a given number of pupils.

After two or three months of war the system was as follows:

The Central Flying School was turning out pilots who were usually absorbed in replacing casualties abroad. There were a certain number of Reserve Squadrons at different stations in England from which Service Squadrons were built up and broken off as they were completed.

Generally speaking, the Service Squadrons carried out the preliminary training of pupils on Maurice Farmans only; these pupils as they qualified were sent on either to the Central Flying School or to a Service Squadron, where they completed their training.

At first, the Central Flying School was equal to the demands made on it by the Expeditionary Force to replace wastage, but as the wastage increased new Service Squadrons at home also had to produce their quota of trained pilots for the Expeditionary Force. The progress of these new squadrons was therefore governed by two factors. First, the output of material on which to train their pilots; and, secondly, the rate at which some portion of their trained pilots was taken away to replace wastage in the field, and eventually as resources became available we had to start Reserve Squadrons to carry out advanced training as well as preliminary.

At this period our two great difficulties were:

(1) A shortage of competent instructors;

(2) Scarcity of aeroplanes and engines;

and we had a very hard struggle to make both ends meet during the winter of 1914-1915, after which matters began to very slowly improve. At the same time the experience of war taught us that a pilot required many qualifications besides those of flying pure and simple.

First, wireless, photography and bomb dropping all came into vogue and demanded extra training. A little later, fighting in the air started, and this involved instruction in aerial gymnastics and the use of machine guns. In the latter half of 1915 fighting in the air became a really serious proposition, and consequently the wastage grew much larger, so much so that during the winter of 1915-1916 the training of pilots had to be considerably forced and hastened in order to keep up with the demands, and the output of new squadrons had to be considerably delayed in order to get training on to a more thorough basis.

The system I have described has been steadily developed until it has reached the organization depicted on the second diagram.

PRESENT TRAINING ORGANIZATION

Observers from France | Civilians, N.C.O.'s and Men recommended for Commissions Cadet Wing | Commissioned Ranks in Army at Home and Abroad

Training Schools
Reserve Squadrons
(Preliminary Training)

Reserve Squadrons
(Advanced Training)

*Service Squadrons | Central Flying Schools

*Service Squadrons

**Includes a Course at the Aerial Gunnery School.*

THE AVIATOR'S TRAINING

Now I will take the career of a civilian who wishes to join the Royal Flying Corps now. He first has to join the Service as a cadet and go through a course in the Cadets' School, at which military subjects, pure and simple, are taught. He gets a grounding of drill and discipline, care of arms, interior economy, military law, and the use of the machine gun; this course lasts about two months. From this the cadet is sent to a Flying Corps Training School, School of Military Aeronautics, where he begins his technical training on the ground. He goes through a course in the care of engines and rigging. He is given some ideas of the theory of flight. He is taught wireless signalling and receiving. He gets instruction in the care of machine guns, in the use of the camera, in map reading, in the observation of artillery fire with models, and in his spare moments he gets a certain amount of drill. This course lasts another two months, and if he gets through this successfully he is given a commission on the General List. He then joins a preliminary training squadron as a pupil and starts his instruction usually on the Maurice Farman, his training both in military and technical subjects going on concurrently. After reaching a certain standard of efficiency and having completed a certain number of hours in the air, he is sent on to an advanced training squadron or Service squadron, where he learns to fly Service types of machines for military purposes, and eventually qualifies for his wings. He is then gazetted as a Flying Officer of the Royal Flying Corps and posted to a Service Squadron. If he shows exceptional promise as a pilot after his qualification he is sent to the Central Flying School, where he is given extra higher instruction on fighting scouts. During the period of advanced training he goes through a course of aerial gunnery away from his squadron. The total time in the air usually required to reach the qualification stage is about thirty hours' solo in present circumstances, but of course the length of time that it takes to reach this standard depends entirely on the weather and the number of aeroplanes available. During the winter it works out to about four months, but in the summer it is considerably shorter.

THE PILOT'S QUALIFICATIONS

The way in which war has forced a higher standard on us is remarkable. Only two and a half years ago, a pilot who flew across country at 3,500 feet and landed without breaking anything was considered to be quite useful. Now the expert pilot has to be prepared to fly at the greatest height his machine will reach, which is sometimes about 17,000 feet, has to dive and loop and side-slip to enable him to be an efficient fighter, and has to have considerable experience in photography from the air, in the observation of artillery fire and the transmission of the results by wireless to the ground, and in the use of the machine gun.

In addition, he must be an expert bomb dropper, which needs considerable practice and experience, and finally in bombing raids, long reconnaissances, and in fighting patrols, it is necessary for aeroplanes to fly in a fixed formation in numbers from two up to twenty, an operation demanding a great deal of skill and experience in the pilot.

There is only one point which has simplified training during this two and a half years: the modern designed aeroplane and the latest engine make flying pure and simple much easier than it used to be. Aeroplanes are usually comparatively stable, and engines have a considerable reserve of power and are far more reliable than in the old days, and these two factors have helped us a good deal in the training of pilots.

To sum up, before the war flying was comparatively difficult, and was the chief factor in the pilot's training, military qualifications being considered of quite secondary importance. Now, flying up to a certain standard is extraordinarily easy, but the standard of military qualifications required is getting higher and higher and more difficult to attain, and at the same time the quality of flying demanded is growing greater every day. So our task at home grows harder.

No Perfect Aerodrome

Now I will just consider the requirements of training on a large scale. First, Aerodromes. There is no such thing as a perfect aerodrome, and even a possible one is very difficult to find in England without either interfering with somebody else's rights or involving an enormous amount of labor and consequent waste of time. Personally, I believe that climatic conditions and a sound soil are the two most important factors when selecting an aerodrome. In England, however, climatic conditions are so varied and unreliable that one can hardly say what part of England is best. Curiously enough, I believe that our farthest North Station has probably been favored with better weather on the whole than any other. So in this country a sound soil is probably the most important factor. After that, if the aerodrome is not a very big one, open ground in its immediate neighborhood is of great importance, so that a pupil whose engine fails just as he is leaving the aerodrome does not have to turn to land but can go straight ahead and land outside. Road communications are also important, particularly at present; if a good aerodrome is selected at some distance from a good road, a very considerable period of time is expended at first in making a road to the aerodrome before the buildings can be fairly started. A debatable point is always how many pupils or how many aeroplanes can be effectively and safely trained and used at one Aerodrome. We have generally assumed that the ideal number was about 60 pupils, and that for 60 pupils, including machines under repair and in reserve, we wanted about 60 aeroplanes; but of late bigger stations have been organized, although I have no statistics to prove which is the better and most economical system. There is only a certain amount of room in the air, and everyone ought to be out in fine weather. An aerodrome, if possible, should be large enough to provide straights of about one mile in length in several directions. The use of these straights accelerates the first stages of preliminary training very greatly, but they are not absolutely necessary, and in a good many of our aerodromes at home no straight exists.

The Instructor's Qualities

The question of instructors has been a very difficult one from the start of the war. I suppose only about 10 per cent. of our flying officers are really good instructors, if as many; but by sheer force of circumstances, except in a few cases, we have been forced to employ practically every fight commander and flying officer who happened to be in England, as an instructor at one time or other. I have often had qualms on the subject, but the results have really been better than I expected originally, and I do not see how we could have progressed as rapidly as we have if we had used only selected officers for instructors from the start. Instructors have many and various methods, and although it has been suggested that definite orders should be issued as to how pupils should be taught to fly, I have never been able to bring myself to issue such an order for fear of hampering initiative.

The qualities required in an instructor are almost precisely the same as the qualities required in a man whose business it is to break in young horses—*infinite patience, great sympathy, good hands, and a clear, steady head.* Instruction in aviation is distinctly trying to the nerves, and my experience is that an instructor cannot be expected to go on forever. Not only is flying dual control with unknown pupils a test on the instructor's courage—the terrified pupils' iron grip—but the mental strain of watching endless pupils take their first solo flight, or waiting for them to get back from the first two or three cross-country trips, is very considerable. It is also hard to convince the good instructor that he is doing more useful work at home than in France. Another factor now is the high standard of military training required, and this to the ordinary human being is almost harder to teach than aviation. The pupil is less keen and the instruction needs more brains. To obviate this trouble, we have, as I have shown you, two schools of military aeronautics, with a staff of specialists, which carry out as much of the instruction on the ground as possible, and a school of aerial gunnery and a school for observers, which specialize in these two objects.

(To be continued)

THE A. B. C. INJECTOR CARBURETOR

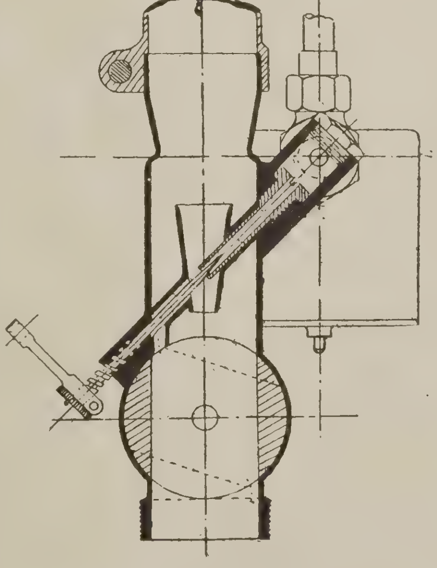
One of the most fascinating problems in connection with internal combustion engines is that of producing the correct gaseous mixture to suit the varying loads upon the engine, and special interest therefore attaches to a new principle in carburetion which has been thought out by Mr. Granville E. Bradshaw, who is well known in connection with A.B.C. Motors, Ltd., of Walton-on-Thames. In the Bradshaw system both compensating devices—for automatically damping out excessive petrol flow with an increased engine speed, and for increasing the suction on the jet according to the amount of throttle opening—are absolutely progressive, and form a straight line curve. The device has been tested under a great variety of conditions and against well-known makes of carburetors, with most satisfactory results.

Before describing the device in detail, it may be as well to state briefly the two general principles which govern the design of all orthodox automatic carburetors. The first concerns the variations in the proportions of petrol and air which occur as the speed of the engine increases. When, for instance, the load on the engine is lessened, the speed increases (the throttle remaining in the same position), the pressure of air in the choke tube is reduced and more petrol issues from the jet. More air also enters the carburetor, but the quantity is insufficient and the mixture becomes rich. The second principle covers the suction on the jet at various throttle openings. As the closing of the throttle would entail a reduction of the suction effect from the engine, arrangements must be made to increase the suction on the jet, and the variation must be regular, or weak and rich periods will be the result.

In the A.B.C. injector carburetor the object has been to get the full value of the injector principle. From the sectional drawing it will be seen that there are two choke tubes, one placed inside the other in such a manner that the other one induces air into the inner one. By this arrangement it is claimed that as the speed of the air into the carburetor increases, a greater quantity of air is injected into the inner choke tube; and as the jet is situated in there, the pressure round the jet—instead of being greatly reduced, as in the usual run of carburetors, thus permitting an excess of petrol to flow—is slightly increased, and the difference in pressure between atmospheric pressure in the float chamber and the pressure in the choke tube is not so great as would otherwise be the case. In this system there is no "dead" point, as the action is dependent upon the speed of air into the carburetor, which varies according to the revolutions of the engine, so automatically correcting for increased engine speed with a given throttle opening.

The adjustment of the suction on the jet according to the amount of throttle opening is obtained by a small slow running tube, which goes from the side of the inner choke tube to a point near to the throttle when this is only slightly open. Consequently at small throttle openings the suction is concentrated on the jet, and as the throttle is gradually opened the suction is lessened in proportion to the opening. Thus there is no "dead" point or any break in the operation.

The size of the jet is controlled by a needle which is designed to be used as an "altitude corrector" when fitted to aircraft engines, or as a dashboard regulator when used on motor cars. It has a primary adjustment in the form of a knurled head, which allows the carburetor to be readily tuned up for any engine; a limited movement is then given to the jet control covering any desired range between very weak and very rich, and the carburetor being entirely automatic this control need not be varied with various throttle openings and engine speeds. If the jet control, for instance, is set to "weak" the carburetion is weak at all throttle positions and at all engine speeds. Similarly if the "control" is set "rich" the carburetion is rich at all throttle position and engine speeds.



A. B. C. injector carburetor.

It is claimed that the arrangement of the control needle in the slow-running tube considerably facilitates starting from cold. If the carburetor is flooded to the smallest extent, petrol will squirt from the main jet into the slow-running tube, where it will remain by capillary attraction until the engine is cranked over. This small amount of petrol mixes with the air existing in the induction pipe and readily forms an explosive mixture. The system of jet control has also the advantage of being adjustable to give an excessively rich mixture, which is of considerable assistance where self-starters are fitted, or in the case of old engines where starting is difficult on account of air leaks past worn inlet valve stems. Incidentally, another point in favor of the jet control is the annular jet, which is less likely to become clogged than a plain hole, and in the event of a piece of dirt making a slight stoppage the jet lever can be adjusted either to remove the obstacle or to give a slightly richer mixture until it is convenient to clean it out. The jet control also permits the use of different qualities of fuel without resetting the carburetor.

Another favorable consideration in connection with the carburetor, especially for aircraft work, is that the risk of fire is greatly lessened, as there are no open ports near to the float chamber, the only air passing into the carburetor entering at the mouth of the hot-air intake.

There are no moving parts in the carburetor, and an entire absence of adjusting screws, orifices, etc., which are so liable to be tampered with. There is only one variable, and that can be adjusted without leaving the driving seat. The simplicity of the carburetor permits of it being of substantial design, and as there are no intricate parts there is practically no liability to accidental damage.

The float chamber is of standard pattern, but is bolted to the side of the main jet boss, so that this can be turned through an angle of 90 degrees. As the jet is at an angle of 45 degrees, the carburetor can be used as a "horizontal" or "vertical" at will, and the level in the jet remains constant for either position.

The carburetor is to be marketed in the following sizes: 20, 25, 30, 36, 42, and 48 mm.

LONG TAILS vs. SHORT TAILS IN AERODYNAMICS

By Prof. G. H. BRYAN, SC. D., F. R. S., Bangor, and S. BRODTESKY, M. A., PH. D., Bristol

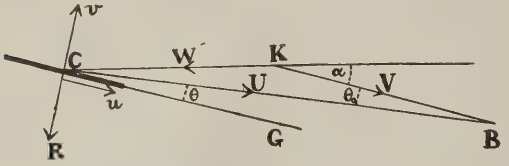
1. Consider any form of aircraft provided with a small rudder plane placed behind its centre of gravity and at a certain distance l from it, which we may speak of as the length of the tail. When this tail is subjected to a given wind pressure, the moment of this pressure about the centre of gravity, tending to turn the machine round, is proportional to l. From this point of view a long tail is preferable to a short one.

On the other hand, the pressure of the air on the tail plane depends on the normal velocity of the wind relative to it. Hence the normal velocity of the plane itself is limited in magnitude, and the angular velocity with which the machine turns about its centre of gravity must therefore be less when l is large than when l is small; that is, the long-tailed machine turns more slowly than the one with a short tail, and this is a disadvantage.

We thus have two conditions which are to a certain extent incompatible, and it becomes interesting and useful to work out a problem in which the joint effect of these conditions is taken into account. In order to avoid complications it appeared to be desirable in the first instance to consider the simplest possible form of system furnished with a tail. The system discussed in the following paper might perhaps be described as a "dart," and may be roughly illustrated by an ordinary arrow. It is assumed to be a heavy body experiencing no resistance itself from the air, and acted on by no forces, but furnished with a rudder plane, the air pressure on which follows the sine law of resistance when the plane is moving in a direction other than tangential relative to the air. In this case the pressure on the tail is wholly employed in overcoming the inertia of the system and changing its motion so as ultimately to bring the direction of motion and the line joining the plane to the centre of gravity into coincidence; or, in ordinary language, to make the system fly in the direction in which it is pointing. The problem presented by an aeroplane or an airship is of course much more complicated, because the pressure on the rudder is largely employed in overcoming the air resistances on the machine itself. In the case of an aeroplane which cannot turn curves without banking, the discussion of the action of a vertical rudder brings us back to the problem of lateral oscillations and lateral stability, while the effect of a horizontal rudder is considered in connection with longitudinal stability.

2. A plane lamina, centre C, so narrow that for moderate angles of attack we may use the sine law for the air pressure and ignore the shift of the centre of pressure, is attached to a system so that the whole mass is M, and the centre of mass is at G, outside the lamina but in its plane. Originally the system is moving with a given velocity V along the lamina and with no rotation. A wind of constant velocity W is suddenly generated at a small angle α with the direction of motion, backwards. To find the oscillation set up, and the best position for the tail, whose size is given. The motion is supposed two dimensional—in the plane of the paper—and there are no applied forces.

It will simplify the work if we consider, not the *actual* motion of the system, but the motion *relative to the air*. The initial relative velocity can be fo the following construction (see Fig.). Measure off CK containing W units length, so that KC represents W, the velocity of the wind; and draw KB parallel to the initial direction of CG containing V units of length, and therefore representing the initial velocity V of the dart. Then CB represents the initial velocity U of the dart relative to the air, and similarly BC, which is equal and opposite to CB,* represents the relative velocity with which the air appears to blow on the lamina initially. The problem of the relative motion thus becomes the same as that of a dart originally projected in the direction CB with a velocity U measured by the length CB. If u v are the relative velocity components of the dart along and perpendicular to the lamina, θ the inclination of the lamina to the fixed direction CB, θ_0 the initial value of θ so that $\theta_0 =$ angle KBC, then we have initially



$$u_0 = U \cos \theta_0 = W \cos \alpha + V,$$
$$v_0 = U \sin \theta_0 = W \sin \alpha;$$

and if α is small, we may take

$$u_0 = W + V;\ \theta_0 = \frac{W}{W+V}\alpha;\ v_0 = W\alpha \quad . \quad . \quad . \quad . \qquad (1)$$

The quantities u, v, θ, define the motion of the dart relative to the air. It is clear, however, that θ represents the *actual* direction of CG at any moment.

3. If CG, the distance of the centre of the lamina *behind* the centre of mass of the system is l, and Mk^2 is the moment of inertia of the whole system about an axis through G normal to the plane of the motion, the equations of motion are as follows:—

$$\left.\begin{aligned} \frac{du}{dt} + v\frac{d\theta}{dt} - l\left(\frac{d\theta}{dt}\right)^2 &= 0; \\ \frac{dv}{dt} - u\frac{d\theta}{dt} - l\frac{d^2\theta}{dt^2} &= -\frac{R}{M}; \\ Mk^2\frac{d^2\theta}{dt^2} &= -lR; \end{aligned}\right\} \quad . \quad . \quad . \qquad (2)$$

where R is the air resistance. As the lamina is narrow, we assume the sine law of resistance and put

$$\frac{R}{M} = Av\,(u^2 + v^2)^{1/2}, \quad . \quad . \quad . \quad . \qquad (3)$$

where A is the reciprocal of a length depending upon the size, shape and aspect of the lamina.

We suppose α small, so that θ remains small for a finite oscillation, and v is also small. We therefore neglect squares and products of $d\theta/dt$ and v; and the equations (2) become:—

$$\left.\begin{aligned} \frac{du}{dt} &= 0; \\ \frac{dv}{dt} - u\frac{d\theta}{dt} - l\frac{d^2\theta}{dt^2} &= -Auv; \\ \frac{d^2\theta}{dt^2} &= -\frac{Al}{k^2}uv \end{aligned}\right\} \quad . \quad . \quad . \quad . \qquad (4)$$

This means that u is constant to the first order of small quantities and equal to U. Eliminating v we get

$$\frac{d^3\theta}{dt^3} + \frac{AU(l^2+k^2)}{k^2}\frac{d^2\theta}{dt^2} + \frac{AlU^2}{k^2}\frac{d\theta}{dt} = 0 \quad . \quad . \quad . \qquad (5)$$

The solution of (5) is

$$\theta = P + Q_1 e^{-\lambda_1 t} + Q_2 e^{-\lambda_2 t} \quad . \quad . \quad . \quad . \qquad (6)$$

where λ_1, λ_2, are the solutions of the algebraic equation

$$\lambda^2 - \frac{AU(l^2+k^2)}{k^2}\lambda + \frac{AlU^2}{k^2} = 0, \quad . \quad . \quad . \quad . \quad . \qquad (7)$$

and P, Q_1, Q_2, are constants defined by the initial conditions.

Measuring the time from the beginning of the disturbance caused by the wind W, we have when $t = 0$,

$$\theta = \theta_0,\ \frac{d\theta}{dt} = 0,\ v = U\sin\theta_0 = U\theta_0,$$

so that at $t = 0$,

$$\frac{d^2\theta}{dt^2} = -\frac{AlU^2}{k^2}\theta_0, \quad . \quad . \quad . \quad . \quad . \qquad (8)$$

to our degree of approximation. After some reduction we find

$$\theta = \frac{\lambda_2 e^{-\lambda_1 t} - \lambda_1 e^{-\lambda_2 t}}{\lambda_2 - \lambda_1}\theta_0 \quad . \quad . \quad . \quad . \qquad (9)$$

It follows from (7) that for a stable oscillation we must have l positive, and when this condition is satisfied, *i.e.*, when the lamina is *behind* the centre of mass of the system, the motion is always a stable one, the system gradually attaining some different steady motion. The ultimate direction of relative motion is along CB. The effect of the tail in this case is to alter the orientation of the dart without affecting its relative velocity. The ultimate orientation is also along CB, *i.e.*, along the direction of the initial relative velocity.

4. The solutions of (7) are

$$\lambda_1,\ \lambda_2 = \frac{AU(l^2+k^2)}{2k^2} \pm \left\{\frac{A^2U^2(l^2+k^2)^2}{4k^4} - \frac{AlU^2}{k^2}\right\}^{1/2} \quad . \qquad (10)$$

The advantage of a very small value of l is that no actual oscillation arises, but a gradual change of direction. But in such a case the decrement of the deviation from steady motion would be slow. In practice λ_1, λ_2, would be con[illegible] so that a damped oscillation ensues. If we write

$$\left.\begin{aligned} \lambda_1, \lambda_2 &= p \pm iq, \\ \text{where}\qquad p &= \frac{AU(l^2+k^2)}{2k^2} \\ \text{and}\qquad q &= \left\{\frac{AlU^2}{k^2} - \frac{A^2U^2(l^2+k^2)^2}{4k^4}\right\}^{1/2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \qquad (11)$$

we obtain for (9)

$$\theta = \theta_0\frac{(p^2+q^2)^{1/2}}{q}e^{-pt}\sin\left(qt + \tan^{-1}\frac{q}{p}\right) \quad . \quad . \qquad (12)$$

Thus at any moment the amplitude of the oscillation is proportional to

$$\frac{(p^2+q^2)^{1/2}}{q}e^{-pt} \quad . \quad . \quad . \quad . \quad . \qquad (13)$$

In order to get the quickest decrease in the amplitude, no attention being paid to the initial extent of the oscillation, we must make p as large as possible, *i.e.*, by (11), we must make k^2/l^2 as large as possible. If, on the other hand, the important thing is to avoid violent oscillations, then we must make $(p^2 + q^2)^{1/2}/q$ as small as possible. This condition easily reduces to $(l^2 + k^2)^2/k^2l$ as small as possible.

5. In an ideal case, where the tail and the connecting rods are supposed to have no mass, k^2 is independent of l. We then get that in order that the oscillation may die down soon, l must be as large as possible. But in order to avoid violent oscillations, we easily find that l must be as nearly as possible equal to $k/\sqrt{3}$. For practical purposes we conclude that *l must be at least equal to $k/\sqrt{3}$* since diminution below this limit involves a double disadvantage.

In an actual flying system, we may expect that

$$k^2 = a + bl^2 \quad . \quad . \quad . \quad . \quad . \quad . \qquad (14)$$

where a and b are known positive quantities. We again get that to make the oscillations die down soon, we must make l as large as possible. In order to prevent violent oscillation, we must have

$$\frac{(l^2 + a + bl^2)^2}{(a + bl^2)\,l} \quad . \quad . \quad . \quad . \quad . \qquad (15)$$

a minimum. This expression is stationary for values of l given by

$$b(1+b)\left(\frac{l^2}{a}\right)^2 + 3\frac{l^2}{a} - 1 = 0,$$

giving the unique possible value

$$\frac{l^2}{a} = \frac{-3 + (9 + 4b + 4b^2)^{1/2}}{2b(1+b)}$$

(*Continued on page 33*)

---

* NOTE.—If the velocities of two moving bodies be represented in magnitude and direction by two sides of a triangle, both drawn *from* their common vertex, then the third side represents their relative velocity. Thus in the above figure where KC and KB represent the velocities of the wind and dart, the relative velocity is represented by CB or BC according to whether we are considering the relative motion of the dart or of the wind. This simple construction for relative velocity can be easily verified by supposing two bodies to start simultaneously from the point K with the velocities W and V; then in a unit of time they will have arrived at C and B, so that the line CB will show the change of relative position in unit time, and will therefore represent the relative velocity. This explanation appears necessary because the treatment of relative velocity in many text books is very confusing, and it is our experience that even *advanced students* frequently make mistakes in consequence.

ACCESSORIES

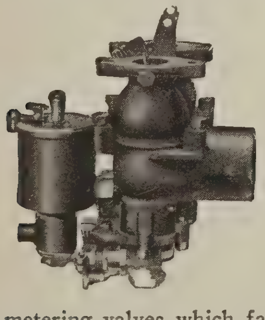
A Spark Plug With Stone Insulation

The difficulty in finding a spark plug which will stand the severe heat and strain incident to use in aeroplane motors presents a problem which is only too familiar. It is for this reason that the plug manufactured by Herz & Co., 245 West 55th street, New York, is of especial interest. This plug is the famous "Bougie Mercedes" of Europe, but is more commonly known here as the Herz Plug. There is no porcelain in its composition, the insulation being of solid stone which is practically unbreakable. In other respects also, Herz & Co. are making a very superior plug. The Clover-Leaf Electrode is an assurance of a highly efficient spark. The plug is self-cleaning, freeing itself from carbon at every explosion, and therefore becomes an actual part of the motor, needing little or no attention after it is installed. The extremely high standard of construction maintained in the making of this plug deserves the highest commendation, and especially where there has been spark plug trouble it will be a good idea to give Herz Plugs a thorough tryout.

Stewart Duplex Carburetor

The new Stewart duplex carburetor for aero motors is of the same principle and design as the regular Stewart duplex with the exception of special details, which have been worked out to make it particularly adapted to aero work in connection with "V" type motors.

The body is of cast aluminum-alloy metal to effect extreme lightness and positive rigidity. This model of the Stewart is known as the racing type, having a complete open air passage around each of the two metering valves which facilitates higher running speeds in the motor.



Requisite to safety in an aeroplane is having the motor under absolute control. The Stewart carburetor with its automatic principle requires practically no further attention after once properly adjusted. However, should ever the emergency arise, immediate control of the carburetor may be obtained through an ingenious dash adjustment extending to the pilot's seat.

The adjustments are so arranged that perfect synchronization is easily obtained between the two blocks of motors. One float bowl maintains a uniform and constant level of gasoline. The butterfly valves are connected on shaft so that in operation each moves to identically the same position, eliminating the possibility of supplying one block of cylinders with more gas vapor than the other.

The manifold flange is cast integral, forming a sturdy and readily accessible connection, making it possible to attach manifolds in straight or off-set position. Trimmings are highly polished nickel and all parts of the carburetor are rust-proof.

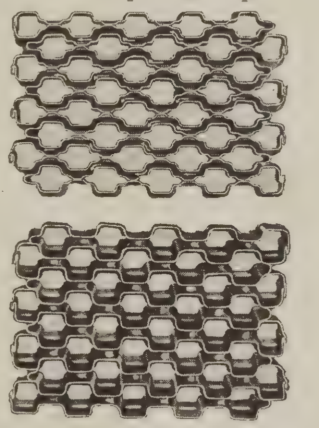
Worcester Pressed Steel Parts

The equipment of the Worcester Pressed Steel Co., Worcester, Mass., enables them to handle parts up to 72 inches long, or 48 inches in diameter, or 13 inches deep, or 1 inch in thickness. Pressed steel parts are made to conform to your particular requirements.

Besides facilities for light and heavy metal stampings, the Worcester Co. has equipment for deep drawing, cold rolling, cold forging, electric and autogeneous welding, plating, pulleys, tubes, strip steel and sheet metal shapes.

Ideal Radiators

The Ideal Staggard Honeycomb Type core possesses all the excellent features which have caused the standard cellular radiator to be accepted as unquestionably superior to other types, combined with many original and exclusive ideal features, while eliminating the one objection to ordinary honeycomb radiators—excessive weight.



Instead of being composed of many hundred individual cellular units, the ideal core is built of strips of tough brass running the entire length, from the top to the bottom of the core. These strips are metallically united every ¾ inch of their length, and the entire core, when completed, is dipped (front and back) into a metal bath. This method of construction produces a core of such lightness, strength and great water capacity, that there is about one pound water capacity to every pound of core weight, and this core is proof against injury by freezing, vibration or any ordinary stresses.

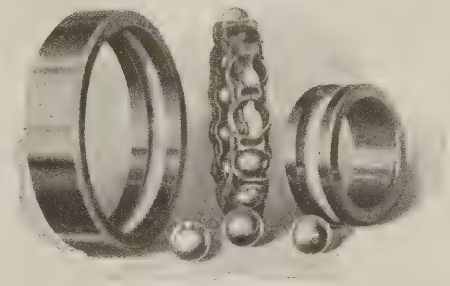
The Staggard or zigzag method of construction used, causes the water to travel about 18 inches to actually progress 12 inches through the radiators. This adds about 30 per cent. to the water capacity and cooling efficiency of the core.

A square foot of 2-inch Ideal core weighs about 7 pounds, holds approximately 3 quarts of water and exposes over 750 square inches of cooling area to the atmosphere by means of over 1,000 ⅜-inch openings. The water travels through the core in 3/32-inch circulating space and, these water channels are cooled on both sides instead of on the outside only, as is customary.

Ideal Radiators are manufactured by the Ideal Sheet Metal Works, Chicago. The upper part of the illustration shows a sectional view and the lower part shows the front view of the cells.

The Fafnir Ball Bearings

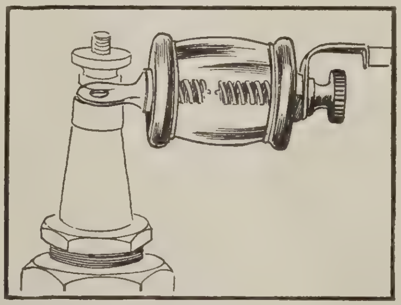
The Fafnir Ball Bearing Company, of New Britain, Conn., took up the manufacture of ball bearings in 1909. Two years were spent in experimental work and the design of special equipment before a single bearing was sold, and their motto has since been "an American product made by American workmanship to the highest American ideals."



The steel used is a high carbon chrome alloy on the same analysis as used by the best European manufacturers. Each individual bar of steel is subjected to test before being machined, and is hardened by special heat treatment and oil quenching, to insure the utmost density and toughness, with a uniformity of steel structure.

Bigelow Spark Intensifier

This little spark plug attachment, illustrated herewith, is attached by simply screwing on the spark plug binding post and to the wire terminal. By merely looking at this device the spark can be seen jumping the gap, so that spark plug trouble is readily detected.



The barrel is made of magnifying glass, and this feature shows up the spark clearly, at night giving a glow like that of an electric light. The intensifier is claimed to overcome all spark plug troubles, making a plug fouled with grease, carbon or soot, or with a broken porcelain, fire perfectly.

RECENT MOTOR PATENTS

1,204,892. ROTARY ENGINE. Walter G. Macomber, Los Angeles, Cal., assignor to Macomber Motors Company, Los Angeles, Cal., a Corporation of California. Filed Apr. 27, 1915. Serial No. 24,196. (Cl. 121—62.) (Illustration No. 1.)

1. A rotary engine comprising a shaft, a cylinder carrier to turn said shaft, cylinders on the cylinder carrier, a stationarily mounted member adjacent one end of the cylinder carrier, a portion of said member extending at an angle relative to the axis of the shaft, a stroke member having bearings at the forward and rear ends of said angular portion of the stationarily mounted member, pistons in the cylinders, pitmen having universal connections with the pistons respectively and having other universal connection with the stroke member, said other universal connections being in a plane extending between the forward and rear bearings of the stroke member, a gear on the cylinder carrier, and a gear on the stroke meshing with the gear on the cylinder carrier.

2. A rotary engine comprising a shaft, a cylinder carrier fixed to the shaft, cylinders secured to the carrier with their axes parallel to the shaft, a standard provided with a tubular extension through which said shaft extends, a stroke member journaled on the extension, pistons working in the cylinders, pitmen having universal connections with the stroke member and pistons, a bevel gear on the cylinder carrier, and a bevel gear on the stroke member engaging the bevel gear on the cylinder carrier.

3. A rotary engine comprising a shaft, a cylinder carrier fixed to the shaft, cylinders secured to the carrier with their axis parallel to the shaft, a standard provided with a tubular extension through which said shaft extends, a stroke member having a sleeve, bearings at both ends of the sleeve to journal the sleeve on the tubular extension, pistons working in the cylinders, pitmen having universal connections with the stroke member and pistons, a bevel gear on the cylinder carrier, and a bevel gear on the stroke member engaging the bevel gear on the cylinder carrier.

4. A rotary engine comprising a shaft, a cylinder carrier fixed to the shaft, cylinders secured to the carrier with their axes parallel to the shaft, a standard provided with a tubular extension through which said shaft extends at an angle to the axis thereof, a stroke member journaled on the extension with its axis of rotation corresponding in angle to the axis of the tubular extension, pistons working in the cylinders, pitmen having universal connections with the stroke member and pistons, a head fastened to the cylinder carrier and journaled on the standard, a bevel gear on the cylinder carrier, and a bevel gear on the stroke member engaging the bevel gear on the cylinder carrier.

5. A rotary engine comprising a shaft having a longitudinal bore and a vent extending from said bore to the periphery of the shaft, a support having a tubular extension to receive lubricant from the vent and having a vent to drain the lubricant from the interior of said extension, a stroke member having a sleeve surrounding and journaled on the extension and provided with sockets, there being ducts extending from the interior of the sleeve to said sockets, cylinders mounted to rotate with the shaft, pistons in the cylinders provided with sockets, and pitmen having hollow balls engaging the piston sockets and having ducts extending from the interior of said balls to interior of the sockets of the stroke member and said balls having vents extending from their interior to the interior of said sockets.

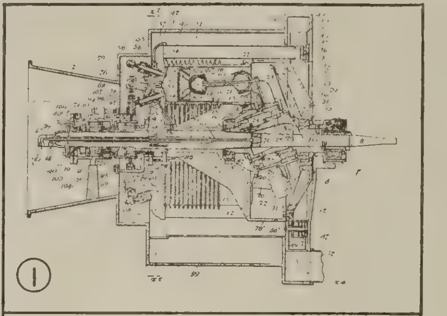
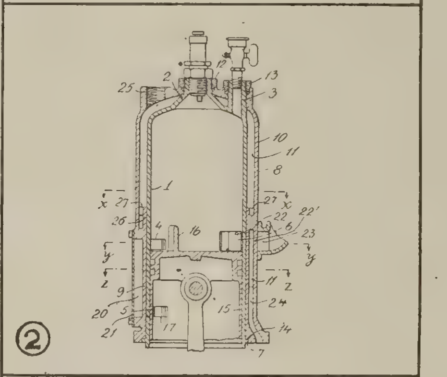
1,210,537. CONSTRUCTION OF CYLINDERS OF INTERNAL-COMBUSTION ENGINES. Edmund W. Roberts, Sandusky, Ohio, assignor, by mesne assignments, to The Roberts Motor Manufacturing Company, Sandusky, Ohio, a Corporation of Ohio. Filed Dec. 2, 1913. Serial No. 804,191. (Cl. 123—193.) (Illustration No. 2.)

1. A jacketed cylinder comprising in combination a cylinder proper, having at one end a projecting boss and at the other end a shoulder, a separately formed jacket fitting over said cylinder and having at one end an aperture through which said boss projects, and at the other end a shoulder engaging the said shoulder of said cylinder, said jacket having, near its said shoulder, a long sleeve portion embracing and fitting tightly a corresponding portion of said cylinder and forming a tight joint therewith, and securing means on said boss securing the cylinder and jacket together.

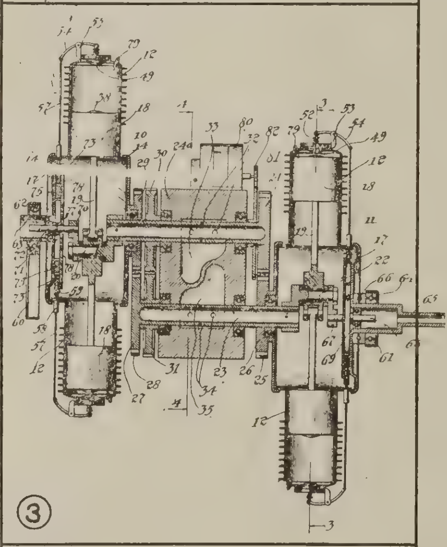
2. A jacketed cylinder comprising in combination a cylinder proper and a separately formed jacket fitting thereover, one portion of said jacket being double-walled, with its inner wall fitting the cylinder closely, another portion of said jacket being single-walled, such single-wall spaced away from the cylinder, the space between such single-walled portion of the jacket and the cylinder constituting a jacket space, said single-walled and double-walled portions of the jacket being integral.



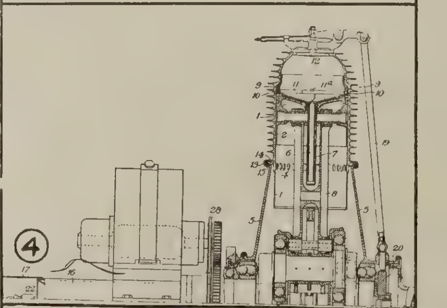
①



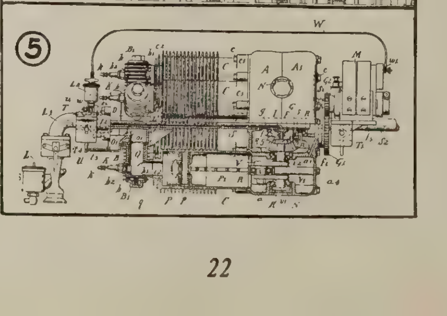
②



③



④



⑤

3. A jacketed cylinder comprising in combination a cylinder proper and a separately formed jacket fitting thereover, one portion of said jacket being double-walled, with its inner wall fitting the cylinder closely, another portion of said jacket being single-walled, such single-wall spaced away from the cylinder, the space between such single-walled portion of the jacket and the cylinder constituting a jacket space, said jacket space in communication with the space between the walls of the double-walled portion of the jacket, said single-walled and double-walled portions of the jacket being integral.

4. A jacketed cylinder comprising in combination a cylinder proper and a jacket fitting thereover, one portion of such jacket being double-walled and having between its walls a jacket space, the inner wall of such double-walled portion fitting the cylinder closely, another portion of such jacket being single-walled, and spaced away from said cylinder, the space between such single-wall and the cylinder constituting a jacket space, said jacket provided with webs connecting the inner and outer walls at points near the end of the inner wall of the double-walled portion of the jacket, said single-walled and double-walled portions of the jacket being integral.

5. A jacketed cylinder for two-cycle internal combustion engines, comprising in combination a cylinder proper having in its sides admission and exhaust ports and a separately formed jacket fitting over said cylinder and having admission and exhaust ports registering with the corresponding ports of said cylinder, a portion of said jacket being double-walled, with its inner wall fitting the cylinder closely, the said ports of the jacket being located in such double-walled portion of the jacket, said double-walled portion extending beyond the region of said ports a distance sufficient to insure a tight joint between the cylinder and jacket, a further portion of said jacket bein single-walled and spaced away from the cylinder, said single-walled and double-walled portions of the jacket being integral.

1,210,409. MOTOR. Thomas P. Brooke, Chicago, Ill. Filed Aug. 1, 1912. Serial No. 712,799. (Cl. 123—44.) (Illustration No. 3.)

1. A motor comprising two sections of cylinders and pistons, one of the sections rotating in opposition to the other section, and provisions whereby the rotation of one of the said sections will actuate the pistons of the opposite section.

2. A motor comprising two sections of cylinders and pistons, one of the sections rotating in opposition to the other section, and provisions whereby the rotation of one of the said sections will actuate the pistons of the opposite section in opposition to the respective section but in the same direction as the actuating section.

3. A motor comprising two sections of cylinders and pistons, one of the sections rotating in opposition to the other section, and piston actuating means operating in opposition to the movement of the respective cylinders and pistons, the piston actuating means of each section being responsive in its action to the operation of the other section of cylinders.

4. A motor comprising two sections of cylinders, rotatable in opposite directions and about different axes, each of said sections operating to counterbalance the gyrational effects of the other section.

5. A motor comprising two sections of cylinders having actuating pistons and rotatable in opposite directions and about different axes, said sections being operatively connected, and means for introducing an explosive mixture directly into each section.

[Claims 6 to 13 not printed.]

1,208,401. INTERNAL-COMBUSTION ENGINE. Felix Joseph Charlemagne Tesse, La Varenne St.-Hilaire, France, assignor of one-half to George Mallison, Eastbourne, England. Filed Apr. 7, 1915. Serial No. 19,844. (Cl. 123—44.) (Illustration No. 4.)
Claims printed in the Patent Office Gazette.

1,215,434. INTERNAL-COMBUSTION ENGINE. Henry L. F. Trebert, Rochester, N. Y., assignor to H. L. F. Trebert Rotary Motor Co., Inc., Rochester, N. Y., a Corporation of New York. Filed Oct. 18, 1911. Serial No. 655,326. (Cl. 123—43.) (Illustration No. 5.)
Claims printed in the Patent Office Gazette.

FOREIGN NEWS

FRANCE

PARIS, March 8.—Willis Haviland and Ronald Hoskier, American aviators, were fighting two Germans over Roye yesterday, without noticing three other German machines hovering over them at a great height.

Suddenly the higher Germans swooped on the Americans. They were forced to dive. When within 5,000 feet the German aviators signaled the earth, whereupon the German anti-aircraft guns opened fire. The Americans escaped, but their machines were riddled with shrapnel.

Walter Lovell and Harold Willis, both of Boston, and Edward Henkle of New York have joined the escadrille at the front.

PARIS, March 9.—Adjutant Ralph Lufbery, the "ace" American aviator in the service of the French, is officially credited with having destroyed his seventh German aeroplane. Lufbery's victorious combat occurred recently. The American flier was the one who put the finishing bullets into the enemy machine.

Conditions in air battling are such that it is often extremely difficult to know definitely to which pilot on the winning side is due the credit for shooting down the foe, especially when several allied and German planes are engaged in the same sector. A banquet was given to Adjutant Lufbery by the pilots of the French squadron in the same sector with the American squadron in honor of his decoration with the Cross of the Legion of Honor. A number of fighting squadrons share the same aviation field with the American pilots.

Each squadron is lodged in a cozy little barracks behind the hangars in which the machines are stored. The American aviators daily make two regular sorties, in addition to various kinds of special and volunteer flying. At first the entire squadron flies between the lines at an altitude of from 1,000 to 3,000 yards protecting the observation machines. This is a very dangerous kind of flying, as the machines are not only within easy range of the German anti-aircraft cannon, but enemy fighting planes are able to swoop down upon them from a superior height and take them at a disadvantage.

The American pilots make another regular sortie, flying far within the enemy lines at an altitude of from 3,000 to 4,000 yards in search of German aeroplanes. Recently they also escorted several French bombing expeditions and fought off attacking Germans. The Americans write that in their sector it has become very hard to find an enemy machine in the air on account of the superiority which the allied aviation corps has established.

Charles Trinkard has been transferred from the foreign legion to the aviation service, and has begun training as a pilot. Trinkard enlisted in the legion in August, 1914, and in the Bois Sabot battle in September, 1915, received two bullets in the right shoulder. After being cured he returned to the front and fought for several months on the Somme front.

George Delpoucho of New York, who was reported killed while fighting as a Legionnaire at Belloy on July 4 last, is now at the front with a French line regiment. He was shot through the body at Belloy and was supposed by his companions to have been killed, but he was taken to a hospital, where he was cured. He has asked to be changed to the aviation corps.

GERMANY

Count Zeppelin is dead. Count Zeppelin is dead, with the dream of his life unfulfilled. It was always claimed by those close to the Count that his ambitions for his aircraft lay not in destroying life, but in linking the new world closely to the old, bringing communication between the two a matter of hours, rather than days or weeks.

The name of Count Zeppelin will always be indelibly linked with the development of those giant air machines to the evolution of which he devoted the best efforts of his long life. He had reached almost the years of an octogenarian, and yet he was seventy years old before he gained any appreciable success in his efforts to perfect a practicable lighter-than-air machine.

Germany stood sponsor for the dream, for the creation that grew out of it and for Ferdinand Count von Zeppelin himself. That some of these giant warcraft have played their part during the present war in the scheme of Prussian, frightfulness is well known to readers of war news. They have crossed the Channel. They have dropped explosives upon London and Paris and have killed scores of inoffensive non-combatants, including women and children. The ranking strategists and tacticians of the Entente Allies, however, contend that as a potential factor among war making forces their influence has been well-nigh negligible. They have succumbed above the land to the attack of the swooping aeroplane and of the aircraft gun, while above both land and sea they have more than once surrendered to stress of the elements.

Though he was a German of the Germans, it chanced to be in the United States that Count Zeppelin made his first balloon ascension. That occurred while he was attached to the command of General Carl Schurz, in the civil war, in the capacity of a German army military observer. A captive balloon in use for military observation by the Union troops greatly interested the young German officer, and he was taken up in it in 1863.

The scion of a wealthy family of ancient lineage, Ferdinand Count von Zeppelin was born in Constance, Baden, in 1838. His childhood home, near Friedrichshafen on the Lake of Constance, was the scene many years later of some of his most successful flights. As a youth he was trained for a soldier's career, receiving his education at the Polytechnic School at Stuttgart, at the Military Academy at Ludwigsburg and at the University of Tubingen. He fought through the Austro-Prussian and the Franco-Prussian wars, and is said to have been the first Prussian soldier to cross the frontier into France in the last named conflict. On that occasion he made a dash across the frontier, it is said, only a few hours after the declaration of war. He was accompanied by only four officers and seven troopers, all of whom were either killed or captured, Zeppelin alone making his escape.

After the consolidation of the German Empire the Count became Plenipotentiary of his native country of Wuerttemburg at Berlin and representative in the Federal Council of the Empire. After serving in the German cavalry for twenty years he attained the rank of general at the age of forty-two. He retired ten years later, a distinguished soldier, to devote all his zeal to the problems of aeronautics.

That study already had engrossed as much of his time as could be spared during the fighting of two wars, though he had given a year to honeymooning with his bride, who was a daughter of the German nobility. It was in 1891 that he began devoting all his time and all his fortune to air navigation. From a wealthy nobleman owning vast estates Count Zeppelin was gradually reduced to an aristocratic mechanic living in a humble cottage on an allowance supplied by friends. He had many narrow escapes from death, and disaster repeatedly overtook his airships.

He had almost become the butt of ridicule. Then in a day it seemed that the adverse tide of years had turned. He electrified a sceptical world in 1898 by ascending from Friedrichshafen.

His monster balloon, 465 feet long, of the rigid type and resembling a huge cigar, soon met with disaster, as had its predecessors. Each wreck was a great financial loss, for the Zeppelin balloons of those days were valued as high as $500,000 each. But Germany now believed in the Count and in his star of destiny. The nation repeatedly rallied to his assistance. When another of his airships was torn from its moorings in gale of wind and wrecked the public subscribed $1,000,000 to a fund, of which the Crown Prince was president, to rehabilitate the inventor. The Emperor frequently helped him out of his difficulties and subsequently the Reichstag appropriated hundreds of thousands of marks for the purchase of his airships for the army.

Even before the European war the record of the development of the Zeppelin was one marked by many disasters. Down to the beginning of the war year, 1914, no less than thirteen of these aerial monsters had come to grief. This is a partial record of the more sensational accidents:

Zeppelin I, as wrecked by explosion August 6, 1908, after being swept from its moorings by storm.

Zeppelin II, was destroyed by a gale April 26, 1910.

Deutschland II, was wrecked by wind while making an ascension at Dusseldorf, Rhenish Prussia. Eight passengers had narrow escapes from death.

Zeppelin VI was destroyed by fire July 3, 1910.

Zeppelin "Substitute Z-1" broke in two, making a landing after a twenty-four hour flight, March 19, 1913.

Z-5 was carried away by storm September 10, 1913, at Leipsic, with a loss of two killed and many injured.

L-1 was destroyed by storm off the Heligoland coast September 9, 1913, with the loss of fifteen lives.

L-11, naval dirigible balloon, exploded at a height of 900 feet above the Johannisthal aviation field, carrying to instant death twenty-six of the twenty-seven men aboard, among them many personal friends of the Kaiser and distinguished officers of the German navy.

Count Zeppelin trained his son, who is also an army officer, in the science of aeronautics and in his method of building dirigible balloons. His daughter, too, became an accomplished aeronaut. She has made more than a hundred flights in the aircraft her father fashioned.

GREAT BRITAIN

According to the official report of March 8, incessant fighting took place in the air above the western front on March 6, in which a prodigious number of German and Allied machines took part. The Germans reported bringing down fifteen machines. The British admit the loss of eleven but say that six German machines were brought down. The British brought about the day of air fights by sending out swarms of aerial observers to photograph and examine the new line on the Ancre to which the Germans have retreated and to prepare for the big operations of the spring. Immediately big squadrons went up to stop them. The report says that the result was satisfactory to General Sir Douglas Haig. The official British report follows:

During the past twenty-four hours there has been no change in the situation. Our artillery silenced hostile batteries which were shelling Ypres. We have again bombarded enemy trenches west of Messines.

There was considerable aerial activity Tuesday, our machines effecting a deal of successful reconnaissance photography and obtaining valuable information. Many bombs were dropped on enemy billets and dumps. The enemy made determined but unsuccessful efforts to stop our work, sending up a very large number of machines.

There was much aerial fighting all along the front throughout the day, during which three hostile machines were brought down and three others driven down damaged. Four of our machines were brought down and seven others are missing.

JAPAN

In view of the backward state of military aviation in Japan as compared with other countries, efforts are being made by the military authorities to effect greater progress in aviation and the extension of the Flying Corps. At present there is only one Flying Corps, stationed at Tokorozawa, and in the Budget for the next fiscal year the Government included a proposal for the establishment of another corps at Kagamihara, Gifu perfecture. Owing to the dissolution of the diet, however, this proposal has been shelved for the time being and unless a new diet is enabled to pass the budget at an extraordinary session after the general election, a delay of another year will take place in the extension of the Flying Corps in Japan.

It is stated that work has been going on for some time at Kagamihara for the laying out of an aviation ground, and the building of an aerodrome and workshop and everything will be completed by March. As soon as the estimates providing for this expenditure are passed by the Diet, the place will become available for use, but until then the establishment will not officially exist.

From *Japan Times*, Jan. 26, 1917:

The Imperial Aero Club which has recently been given 10,000 yen by Mr. Soga in Osaka is now spending the money in the construction of an aeroplane for looping purposes. The machine under construction will on completion be equipped with a 90 h.p. engine and be piloted by Mr. Ozaki, the son of Mr. Ozaki, the ex-Minister of Justice. Mr. Ozaki is not a fancy flyer at present but he intends to learn looping the loop in this machine.

Japan Times, January 21, 1917:

Miss Katherine Stinson, the American flyer, is now staying in Kyoto as a guest of Miss M. F. Denton, of the Doshisha Girls' School. On Thursday morning Miss Stinson gave a lecture for students of the Dohisha Girls' School on the subject of "How I Became An Aviatrice." She will go to Kobe to-day where she will catch the O. S. K. liner Tacoma Maru for Manila on January 22.

The Formation of Model Clubs

To form a model aeroplane club at least six interested persons are necessary. As soon as a place in which to hold meetings has been decided upon the club should proceed to elect a Director whose duty should be to manage the affairs of the club. One of the first things to be considered is the name under which the club will operate; the custom is usually to adopt the name of the Town or City in which the club is located, viz.: Concord Model Aero Club, Concord, Massachusetts, although it is the privilege of the majority of the members to choose a name such as they might feel will best benefit the purpose for which the club was organized. As in the case of the Aero Science Club of America, this club was formed for the purpose of stimulating interest in model aeronautics and to help those who might become interested therein, not only in New York City but throughout the entire United States.

When the matter of name and place has been settled the club should decide upon the course it is to follow, first by electing OFFICERS and second by preparing a CONSTITUTION AND BY-LAWS. In the case of clubs whose membership does not comprise more than six members it does not seem desirable to have more than one officer, namely, a DIRECTOR, who might perform the duties of a President, Treasurer and Secretary until the Club has reached a larger membership. In this way the members are enabled to concentrate upon the construction and flying of models and to engage in such other activities as to carry out the purpose for which the club was organized. However, the foregoing is merely a suggestion on the part of the writer, who by the way is a member of the Aero Science Club of America and formerly acted in the capacity of Secretary to that club.

Clubs who membership totals more than twelve, however, should proceed to elect a President, Treasurer and Secretary, all of whom must receive a vote of at least two-thirds of the membership. With clubs of this size a Director is not needed as the affairs of the Club are usually entrusted with the governing officers, the President, Treasurer and Secretary. In as much as the Constitution and By-Laws are an important factor in the affairs of any model club, the governing officers, before mentioned, should hold a private meeting, at the earliest moment whereat to frame a Constitution and set of By-Laws embodying the purposes and policy of the Club. When the proposed Constitution and By-Laws are completed they should be presented to the members for approval after which a copy should be given to every member.

The following is a specimen of Constitution and By-Laws that might be used by any person or persons desiring to form a Model Aero Club:

Constitution and By-Laws of a Model Aeroplane Club

ARTICLE 1. NAME: The name of this Club will be known as The..............Model Aero Club.

PURPOSE: The object of this Club shall be to study and increase the interest in the science of Aeronautics in every way possible and to realize out this object, shall construct and fly model aeroplanes, glides and man carrying machines. FURTHER, Contests shall be held for model aeroplanes and prizes awarded to the winners thereof. And as a further step in the advancement of this art meetings, lectures, discussions, debates and exhibitions will be held.

ARTICLE 2. MEMBERSHIP: Any person may become a member of this club provided his application receives the unanimous approval of the majority of members, or is passed upon by the Membership Committee. A member may resign his membership by written Communication to the Secretary who shall present it to the Membership Committee to be passed upon.

ARTICLE 3. OFFICERS: The Officers of this organization shall be a President, Vice-President, Secretary and Treasurer and a Board of Governors to consist of said Officers. The President and Vice-President shall constitute the Executive Committee of the Board of Governors, with full powers to act for them in the affairs of the Club. The election of officers shall take place at the first meeting held during the month of .... of each year and shall hold office for one year. In the event of a vacancy occurring in the office of the President the vacancy shall be filled by the Vice-President or next highest officer present. Any other vacancy shall be filled by a temporary officer appointed by the President. The president shall preside at all meetings of the Club and of the Board of Governors, and perform such other duties as usually pertain to that office. The president shall have full authority to appoint Committees or Boards as may be necessary to further the interests of the Club.

The Secretary shall keep a record of all meetings of the Club, Board of Governors and Committees and shall use the seal of the club as may be directed by the Executive Committee. Further, he shall issue notices to officers and members of all special meetings and perform such other duties as may be assigned him by the Constitution, by the Club or by the Board of Governors.

The Treasurer shall have charge of the funds of the Club, receive all moneys, fees, dues, etc.; pay all bills approved by the Board of Governors, and preserve all proper vouchers for such disbursements.

(To be continued in our Issue of March 26th)

Illinois Model Aeroplane Club

A meeting of the Illinois Model Aero Club was held in the rooms of the club, March 2, 1917. Mr. Wm. Sprague read the report of the contest committee announcing a special meeting to be held March 9, at which contests in duration and speed for models having a motor base of seven inches or less would be held. Mr. Wm. Schweitzer gave the report of the membership committee and told of a new club which he was organizing at his school.

The club then had the pleasure of having several talks by well-known men who had attended the Pan-American Exposition in New York. The speakers, Mr. Walter Brock, the prominent aviator, Mr. Muffly and Mr. Hoffman gave very interesting accounts of the exhibit. An unusually large number of members and friends were present.

On March 9th the special contests for seven-inch models was held in the large banquet hall of the Auditorium Hotel. The speed contest was won by P. Breckenridge, whose model averaged twenty miles per hour. The duration contest was won by B. Likosiak with a flight of six seconds. Most of the flights were stopped by striking the walls long before their power was exhausted. A contest for paper gliders was then held in which every boy and man present entered. Ribbons were awarded to the winners of these contests.

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Anent Records

One thing we must say in our own favor—we have never hesitated to hold contests for aeroplanes, award prizes and invent machines. Of course, we will admit that these things are purely matters of the imagination, but nevertheless if there is half as much fun in reading them as there is in writing them the object is fulfilled. Now in order that the sky may not be cluttered up with all sorts of aeroplanes, dirigibles, helicopters, ornithopters, balloons, etc., we are going to issue a specification form which we hope may be followed by the authorities in the future. (Of course, we really have no idea that they *will* be followed but at least we can suggest them.)

In the first place we would make the rule that no more than 100,000 machines may be bought by the Army and Navy in one year, because if that limit were exceeded, there might not be enough machines left for private sportsmen. Then we would have a rule that the publicity agents of no aeroplane company could break any record more than eight or ten times in a year. For the way these press departments shatter records is something astounding! Most any day we can pick up a paper and read something like the following:

"Aviator Whois, is about to break the altitude record in a Whatsis machine, with a Nonesuch motor of a few thousand H.P." Or in this manner: *"Suzie Aerofoil, the darling girl aviatrice, intends to break all existing records for duration this spring. She is being managed by that wonderful publicity man, J. M. Rushinprint."* Now that is what we are complaining against. What good are our old faithful records if rash people insist on breaking them all the time? Next we would limit the number of consecutive loops made by any one aviator to thirty, for the way these exhibition men are looping is extraordinary! Some years ago we were thrilled when some aviator went aloft and by a combination of skill and good fortune managed to land again with his frame intact. But now? Are we satisfied to see a simple flight well executed? Are we? We are not! We must see side-slips, dives of death, loop-the-loops, upside-down-back-reversible-side flying. The worst of it we encourage these men. When a report comes in that Aviator Somebody has looped the loop ninety-five times in percussion without blinking an eyelash, we applaud feebly and murmur, "Huh! That's not so much; why, I remember way back three years ago when that feller, I can't remember his name, flew upside down for three hours, yes sir, *three hours.* Of course, we know we are not telling the truth. But we must refuse to believe that anything is better than it was in the olden days. So the aviators explore the record books, looking for new records to break. If every record has been fractured beyond recognition and they are hard pressed, why they just invent some new competition and establish a record in that.

Now, if this thing goes on like this, why before long the records will all be so wonderful that they can never be broken again, and that will take all the zest out of flying. We will fly so high that the force of gravity will be lost and we will glide off into regions celestial. We will fly so fast and so far that we will meet ourselves coming back the other way. Just think of the possibility of a terrible accident when a fellow is flying so fast around the world that he even exceeds his own expectations and bunks into himself on the way back!

And we must limit the greatness of all the constructors. Every day a manufacturer announces that he has just completed the greatest machine ever built. Now with hundreds of aeroplane manufacturers in the world each turning out the greatest machine ever built every day, before long each machine will be better than the one better than it, every machine will be faster than a faster machine, every aeroplane constructed will be the largest in the world, and Lord knows where we will stop. We will have achieved the infinite, reached the ultimate development, and exceeded the bounds of reason. We will have improved so much that we cannot better our product and then will be forced to build nothing but inferior machines!

Is that not a sad thought?

Our Own Technical Department

I. X. L. We do not know what Monosoupape engine is, but we suspect that the name is French for "Pesky."

M. B. A. "Stationary Engine" may be used to describe almost any motor, when it refuses to run.

O. P. K. To find the horse-power of any motor, look it up in the prospectus of the company, divide the answer by six, and use three engines where one is called for.

R. A. T. The reason that the "3 in 1" control is not used any more is that it was found to be very oily.

E. S. D. Never land a flying boat anywhere except in the water.

P. O. I. We doubt very much if the United States Army could use your invention, but you might try the Long Island Institution for the Feeble-Minded.

P. A. W. The term "Aviation Section" is used because "section" means a small part of something.

W. S. Q. The first airship owned by the United States Navy is called "D-N 1." As you have suggested in your interesting letter, perhaps the members of the crew will supply the missing letters in the name.

S. A. W. There is no reason to believe that a triplane is three times as fast as a monoplane.

P. A. O. We are sorry to disappoint you, but matrimonial questions are entirely too acute and technical for this department.

W. Q. A. The formula for that cheap gasoline you bought is H^2O.

"YA WOULDN'T THINK THAT PARACHUTE WOULD HOLD A FELLER LIKE BILL"
"I SHOULD THINK TH' BLOOD WOULD ALL RUSH TO HIS HEAD, WOULDN'T YOU?"
"GRACIOUS!"

and 174 H.P. at 1450 r.p.m. Weight of motor, 307 kgs. A complete description of the Mercedes engine was given in the September 11, 1916 issue of AERIAL AGE.

The propeller is direct driven and of two captured, one made by Heine, Berlin, had a diameter of 280 mm. with 190 mm. pitch, and another, labelled "Intergal—J. P. W.," had a diameter of 270 mm. and a pitch of 140. The former propeller was made of walnut and mahogany, and the latter of walnut, ash and sycamore in alternate laminations. Weight of propeller 19 kgs.

The gravity tank is V shaped to conform with the slight dihedral of the upper plane. It is fitted between the foward and rear wing beams and attached to the central inverted V struts from the fuselage. A filler pipe projects above. The gravity tank has a capacity of 26 litres and the main tank 195 litres. A three-way tap permits the motor to be fed either under pressure from the main tank, or by gravity. An oil tank as placed on the right of the motor and has a capacity of 20 litres.

The radiator is located just forward of the gravity tank, in the upper plane. It fits in a space provided for it between the forward main spar and the leading edge of the plane.

Fuel is carried weighing 170 kgs. Water, 25 kgs.

instruments could be checked. For measuring the thrust ordinary spring balances were used, a heavy one being employed to measure the thrust of the propeller when driven by the engine, and another lighter one to record the head resistance of the engine when the propeller was driven by the electric motor *k* (Fig. 12), driving a blast of air on to the engine.

Apparently this head resistance was merely measured as a matter of interest, and not because it was important. As stated previously, the engine as a rule is built in the fuselage, and possesses little or no individual head resistance. However, the apparatus lent itself to obtaining, in a simple manner, figures for the head resistance, and these were therefore taken.

The electric motor *k* shown in Fig. 12 was of the kind in which the field can turn against the resistance of weights carried upon an arm, so that the power passing through it can be very accurately measured without reference to efficiency curves. This motor required to have a capacity up to 150 h.p., and apparently it was a very delicate instrument not easily obtainable. Although five test cradles were erected, it was only found possible to obtain one of the test dynamo motors *k*. Rails were therefore provided for transporting the electric motor from one cradle to another, and this and the truck appear in Fig. 12.

To obtain the torsional resistance due to air churning in the case of rotary engines, a dummy engine was made, and this was driven by a separate electric motor mounted upon the cradle and the necessary figures obtained. It was assumed that the loss by churning is about 10 per cent. of the engine's output, and therefore a 15 to 20 h.p. motor was provided for. For cooling the rotary air-cooled engines the fan *n* was used, driven from the motor *m* (Fig. 14), which delivered air at about 20 meters per second.

Burgess Training Hydroairplane

Among the many models of Airplanes, Seaplanes and Flying Boats produced by this company the new "U" type Hydroairplane meets a very pressing need—an efficient, well-balanced flying machine of conventional type and low power for militia training purposes.

The Massachusetts Naval Militia has the first one now in service.

Standard Deperdussin control in duplicate; Curtiss OXX-2 motor; simple float; light, sturdy construction; large speed range (forty to sixty-eight miles per hour); are characteristics necessary to the hard service required for training purposes.

Hydroplanes and pontoons designed and manufactured for airplanes of every type, including Curtiss, Sturtevant and other makers.

Designers and constructors for the U. S. Army and Navy and British Admiralty.

Suggestions for Recording Field Tests

Attention is called to the very timely paper on "Suggestions for Standard Tests of Aeroplanes" by Mr. Jno. J. Rooney, Aeronautic Engineer of the Wright-Martin Aircraft Corp., read at a recent meeting of the S. A. E. and published in the February 12th issue of AERIAL AGE. In the article it is pointed out that the aeronautical industry in this country is not making the progress it should, and as an aid to progress more scientific methods should be used in making field tests of aeroplanes. It is, of course, urgent that immediate steps be taken to improve these methods.

Form IV of Mr. Rooney's paper, which is given below, contains a systematic collection of data necessary to be records in such tests. As this field test record is the most complete form that has so far been suggested, it is hoped that manufacturers will realize the advantages to be gained by closely following it.

(*Continued from page* 21)

Thus the oscillation is least violent for

$$l = \left[\frac{a \left\{ -3 + (9 + 4b + 4b^2)^{1/2} \right\}}{2b(1 + b)} \right]^{1/2} \quad . \quad . \qquad (16)$$

since this makes (15) a minimum. In practice this value of l would be a lower limit.

When b/a is small, (16) becomes approximately

$$l = \frac{\sqrt{a}}{\sqrt{3}} = \frac{k}{\sqrt{3}} \quad . \quad . \quad . \quad . \quad . \qquad (17)$$

agreeing with the result previously found.

6. Since θ ultimately vanishes it will be seen that the direction of motion ultimately becomes parallel to CB, and this therefore represents the direction of the asymptote of the path. It is, however, important to determine the distance of this asymptote from C, as this represents the total displacement of the dart in a direction perpendicular to CB relative to the air. This displacement is obviously equal to

$$\int (u \sin \theta - v \cos \theta)\, dt \quad . \quad . \quad . \quad . \qquad (18)$$

which for our purposes of approximation may be taken to be

$$\int (U\theta - v)\, dt$$

Now from equations (4) we obtain

$$\frac{dv}{dt} - U \frac{d\theta}{dt} = \frac{k^2 + l^2}{l} \frac{d^2\theta}{dt^2} . \quad . \quad . \quad . \quad . \qquad (19)$$

This is the equation obtainable by taking moments about the centre of the tail. It follows from this that the total displacement is equal to

$$-\frac{k^2 + l^2}{l} \theta + C_1 + C_2 t \quad . \quad . \quad . \quad . \qquad (20)$$

where C_1 and C_2 are constants. But since the initial velocity perpendicular to CB is zero and θ is initially equal to θ_0, the total displacement becomes equal to

$$\frac{k^2 + l^2}{l} \theta_0 \quad . \quad . \quad . \quad . \quad . \qquad (21)$$

This is a minimum when $l^2 = k^2$. If, however, $k^2 = a + bl^2$, the condition for a minimum becomes $a = bl^2 + l^2$ and therefore $k^2 \doteq (1 + 2b) l^2$. In any case there is a certain length of tail for which the displacement is least.

If, however, we consider the total displacement of the *centre of gravity* we must subtract $l\theta$ from the above amount, and the total displacement sideways now becomes equal to $\theta_0 k^2/l$, showing that a long tail is the best.

It is easy to obtain a generalisation of this last result for the case of any kind of aircraft whose motion may be treated as two dimensional. In such a case there is at every instant a point on the axis of the system through which the resultant air resistance passes. This point takes the place of C the centre of the tail. The main difference is that since the components of air resistance depend both on the linear and angular velocities of the system, and these are not in general proportional throughout the motion (for v is initially finite and $d\theta/dt$ initially zero), the distance of this point from G, which we have hitherto denoted by l will now be variable. The total displacement of G at right angles to the direction of final motion will now be

$$= -\iint \frac{k^2}{l} \frac{d^2\theta}{dt^2}\, dt^2 . \quad . \quad . \quad . \quad . \qquad (22)$$

We may write this equal to $k^2\theta_0/[l]$ where $[l]$ denotes some quantity such that $1/[l]$ is intermediate between the greatest and least values of $1/l$. In any case it is advantageous from this point of view that $[l]$ should be large.

7. The preceding investigation of the small oscillations is, however, only a particular case of the more general problem of aeroplane stability. A more useful estimate of the initial action of the tail plane can be obtained by expanding θ in powers of the time by means of the exponential series. We thus obtain from (9)

$$\frac{\theta}{\theta_0} = 1 - \frac{\lambda_1\lambda_2 t^2}{2!} + \frac{\lambda_1\lambda_2(\lambda_1 + \lambda_2)t^3}{3!}$$
$$\frac{\lambda_1\lambda_2(\lambda_1^2 + \lambda_1\lambda_2 + \lambda_2^2)t^4}{4!} + \quad . \quad . \qquad (23)$$

Making use of the formulæ for the sum and product of the roots of the quadratic (7) this gives

$$\theta_0 - \theta = \frac{AlU^2}{k^2} \theta_0 \left\{ \frac{t^2}{2} - \frac{AU(l^2 + k^2)}{k^2} \frac{t^3}{6} \right.$$
$$\left. + \frac{AU^2\{A(l^2 + k^2)^2 - lk^2\}}{k^4} \frac{t^4}{24} - \dots \right\} \quad . \qquad (24)$$

This equation shows that the initial angular acceleration of the system is greatest when l is large, but in this case the angular acceleration decreases more rapidly than it would do if l were small, thus confirming the general statements at the commencement of the present paper.

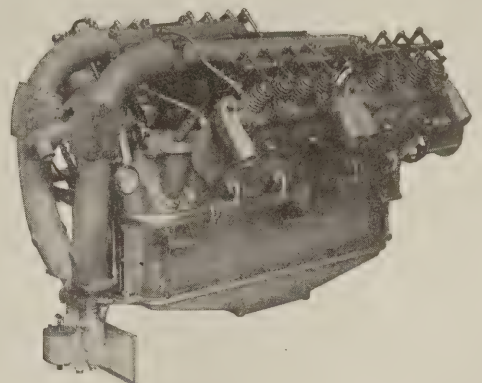
Aluminum Aeronautical Motor



140 Horse-Power

An important change in Design and Construction of the Standard Eight-Cylinder Motor has effected:

Elimination of Cast Iron. **Higher Efficiency.**
Better Accessibility. **Increased Reliability.**
Weight Reduction of One Hundred and Thirty Pounds.

These features have been proven by Service Tests during the past eight months

Prompt Deliveries Assured

B. F. STURTEVANT COMPANY

Hyde Park : : : Boston, Mass.

Above All:--Strength

The knowledge of strength engenders confidence, and the direct result of confidence is the will and power to excel. No matter from what angle we consider the aeroplane and the dirigible, STRENGTH is of paramount importance, completely overshadowing other characteristics of the machines of the air.

It is but common knowledge that a chain is as strong as its weakest link, and it is not stretching the point to say that the aeroplane is efficient, strong and sturdy as its fittings and special parts.

STRENGTH, however, is not mere bulk, brute power, or weight. Anyone could build strong fittings,—but the fittings would undoubtedly be far too heavy for the modern machine. Strength, then, in the aeroplane, must be the result of scientific research, absolutely the finest of materials, and *hairline precision.*

ACCURACY can result only from long experience at a task, and conscientious adherence to the scrupulous performance of it.

SERVICE is obtained in direct proportion to the knowledge, skill, materials,—and *conscience* put into the manufacture of a product.

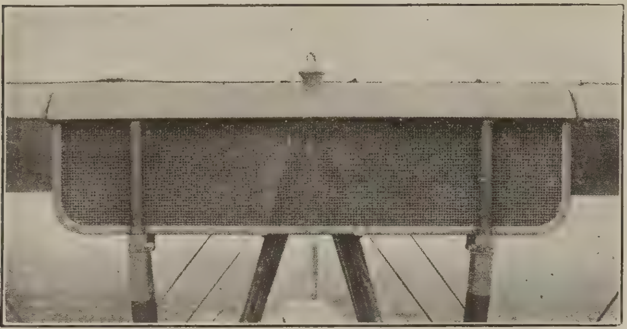
The Erie Specialty Company is now supplying Screw Machine Products and Aluminum Castings to the leading aeroplane companies:—the aeroplane companies which desire the finest fittings and special parts that modern science and skill can produce.

Every part that leaves the factory of the Erie Specialty Company is tried, tested, and proved perfect.

We shall be glad to hear from those manufacturers of aircraft whose desire is for Screw Machine Products and Aluminum Castings which are accurate, strong, and efficient. Tell us your requirements and we will submit estimates and early delivery dates.

ERIE SPECIALTY COMPANY

ERIE, PENNA.



TYPICAL of the practical correctness of many innovations introduced by Sturtevant aeroplanes, is the small light radiator which fits neatly into the top wing. The circulation system is greatly improved, and the weight and resistance reduced by this simple and efficient solution of a difficult problem.

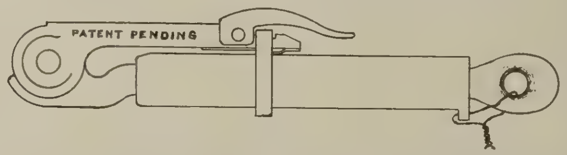
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

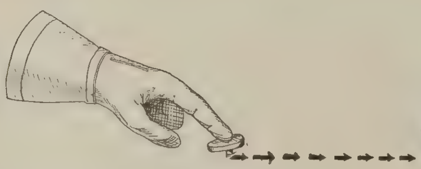
HESS-BRIGHT BALL BEARINGS

FROM the President down, there is a feeling in our plant that we are doing things of which anybody could be justly proud. WE ARE MAKING A "BETTER" BALL BEARING.

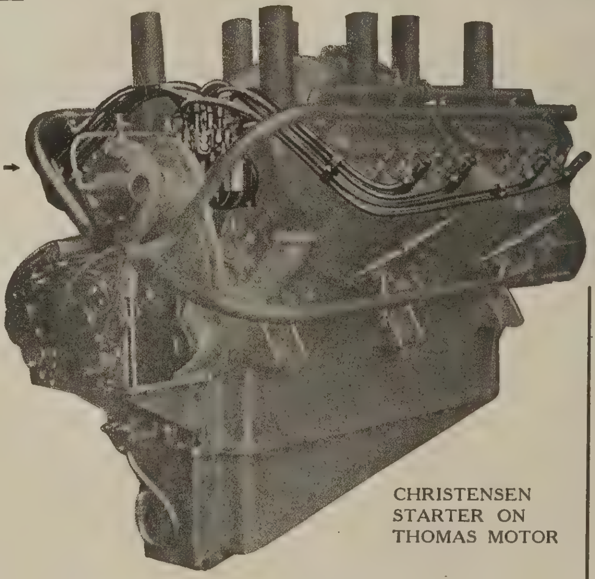
Something accomplished — something done — done painstakingly and thoroughly,—this is the spirit that prevails throughout our entire organization. That is why HESS-BRIGHT BALL BEARINGS are "BETTER."

HESS-BRIGHT BALL BEARINGS are what they are because each and every individual connected with this Company, no matter in what capacity he may be, is all the time endeavoring to help make a superior bearing.

The Hess-Bright Manufacturing Co., Philadelphia, Pa.



The Touch of a Button AND She Goes:—*Instantly!*



CHRISTENSEN STARTER ON THOMAS MOTOR

A Self Starter that combines unfailing action with simplicity and light weight; a Starter that cannot be put out of commission by excessive vibration; a Starter that is absolutely dependable, regardless of weather conditions or altitude.

Christensen Automatic Motor Starter

THE marked efficiency of the Christensen Self Starter is perhaps best suggested by the results of a test on a Hall-Scott Motor made at the plant of the Standard Aero Mfg. Co., at Plainfield, N. J. There on a tank of air of 250 pounds pressure, **28 complete starts** were made **without recharging the tank,** and the last start was made on the low pressure of 100 pounds.

Curtiss J. N.
Tractor
Equipped With
Ackerman Wheels

"IT'S IN THE SPOKES"

AFTER four years' exhaustive tests, The Ackerman Wheel Company offers to aeroplane builders a wheel of special design that will solve many of the difficulties hitherto encountered.

In a series of laboratory tests (see illustrations below) the wheel was attached to a large case, into which was loaded 1,500 pounds of sand. A side thrust blow, with the wheel seven feet removed from the point of contact, was calculated to give the wheel a stress of 27,000 pounds. This was when the wheel struck the plain floor surface. To test the wheel to its maximum, two cleats of wood were nailed to the floor, four inches in advance of the striking point, and under this test four spokes of the wheel were broken. Calculation showed that the energy of the blow totalled 49,800 pounds.

A special alloy, specially treated, is used to meet all conditions that the wheel can be subjected to. The steel receives a special process in the treating, so that it will give the required resiliency, starting at the center of the curve and gradually growing stiffer and stronger both to the hub and relative to the structure of the spoke. The spokes being made on the curve, they are hung on the hinge at the rim, being a unit in the hub, allowing them to open and shut according to the load placed on the hub.

In the aeroplane wheel it is found that the hub will leave the center four inches when maximum loaded, and return to center as load is decreased, without the springs taking a set. There has never before been a wheel invented which would meet any such conditions.

These wheels can be built according to size and weight of any load from 500 pounds up to 5 tons

VOL. V NEW YORK, MARCH 26, 1917 No. 2

QUICKEST WAY TO PREPARE DEFENSE OF UNITED STATES AGAINST INVASION IS TO DEVELOP LARGE AND POWERFUL BATTLEPLANES

REAR ADMIRAL FISKE, whose inventions and achievements rank him with the leading naval authorities of the world, in a memorandum to Mr. Alan R. Hawley, the president of the Aero Club of America, points out that one hundred large battleplanes carrying 3-inch guns would afford the defensive power of about 60,000 rifles.

As Admiral Fiske has ably pointed out, the battleplanes would afford a combination of power and mobility easily obtainable and thus solve easily the problem of quickly building our defenses. Shots from 3-inch guns carried by these battleplanes would sink destroyers, transports and submarines and prevent the landing of troops on American soil, when nothing else could.

Can these battleplanes be obtained? The answer is in the affirmative—and AERIAL AGE will tell in a coming special number all about large battleplanes and the prospects of obtaining them in the near future.

Admiral Fiske's memorandum reads as follows:

"In view of the backward state of our defenses, especially on the land, I would like to suggest the advisability of considering whether it is not possible to devise some means that is powerful and easily gotten, in order to supplement our present means: Something that can do for our army and navy service a little like what the Monitor did in 1862. The exigencies of the Civil War, especially the menace given by the Merrimac, caused the hurried building of the Monitor, which Ericson had been trying to have built for several years. The Monitor fulfilled her mission perfectly. Had the Monitor not been built, the Merrimac would have prevented the blockade of the southern coast, the south would have been able to sell her cotton; would have received money, munitions and equipments in exchange, and would probably have been recognized by some of the European powers, and been able to resist successfully the armies of the north. It was the Monitor that cast the deciding vote in our Civil War.

"As the submarine threatens to cast the deciding vote in the present war and as the Monitor has been expanded into the dreadnought, it may be profitable to ask what is the inherent cause of the efficiency of those weapons. Clearly it is the same cause as makes any weapon efficacious; that is concentration of great power in a small space, combined with great mobility. The combination permits of the application of great force on a given spot at a given time.

"In 1911, I published an article called "Naval Power," in the United States Naval Institute, in which I pointed out this fact, and suggested what a battleship on land could accomplish, if such a thing could be constructed. The *Popular Science Monthly* republished this suggestion in November, 1915, and a few months later, the so-called British tanks appeared, which are small land battleships.

"Now the unevenness of the ground is a great obstacle in the way of making land battleships very large and fast, and seems to prevent armies from using units as powerful and swift as navies use. This is unfortunate for a country like the United States, for two reasons: One reason is that the length of our boundaries on the ocean and on our northern and southern frontiers is so great, and the average distance to the boundary from places within the country is so great, that it would be highly advantageous for us to be able to move powerful units at great speed; another reason is the natural inventiveness of our people would enable them to produce very effective land battleships, if the difficulties were not absolutely insuperable—as they seem to be.

"My life in the navy brought me into intimate contact with all the advances in naval construction—from the little Saratoga in which I made by first cruise as cadet midshipman to the superdreadnought Florida, which was my last flagship. The military value of concentration was of course impressed unceasingly upon me, and with it a realization of the fact that the main aim of strategy and tactics is to bring a preponderatingly force to bear on a given point, before the enemy can prevent it. To do this, we need concentration of power in as few units as possible, and ability to move those units as rapidly as possible. POWER AND MOBILITY ARE THE PRIME AGENCIES OF THE MILITARY ART.

"Now at the present time the unit in all armies is the soldier and his musket. We seem tied down to that slow and feeble little unit. But are we really? The navy seemed tied down to the little sailing frigate; so much so that even after the Montor's achievements in our civil war, we returned to the sailing frigate. The competition of nations, however, forced us to take up larger units, and now we have the Pennsylvania.

"Is there no way in which this greate inventive and constructive nation can get some more powerful and mobile unit than the soldier and his rifle? Can we not get more defensive usefulness out of the intelligent collegian, technician or chauffeur than by marching him in a regiment with a little musket in his hand? Is there no device by means of which large units of power can be carried which is not subject to the limitations of speed and size that restrict a land battleship to small dimensions?

"Yes, and that device is now being used in Europe, after having been designed and manufactured in the United States. It is called the battleplane. Such a device recently carried 27 passengers, and another, an air cruiser, carried 3500 lbs. of crew and equipment. Some of the largest battleplanes are being constructed in the United States and one of the aeroplane manufacturers states that he can easily build a battleplane capable of carrying and launching a full size torpedo weighing 3500 pounds.

"If battleplanes have a field of usefulness in Europe, where the distances are very small and where the organization, training and strategical employment of large armies have reached a high state of development, do they not have a much wider field in the United States, where the distances are relatively enormous, and where the organization, training and strategical employment of large armies are arts almost unknown? Is it not possible that an immediate and strenuous development of battleplanes might save us from invasion, just as the Monitor saved us from the Merrimac?

"In case our fleet is defeated in the Atlantic during the next year, we shall not have an army that could stand up against any European army that might land on our shores. But if we had a division of say one hundred battleplanes near New York, costing about three million dollars, we could certainly prevent the disembarkation, transit in boats to the shore, and landing of any force of soldiers, especially if the battleplanes were assisted by say two hundred small aeroplanes, dropping bombs. Similar divisions at other points, including one at the Panama Canal, could perform similar services, and the great speed of the air craft would enable each division to guard a long extent of coast. A division of 100 battleplanes could go from New York to the Capes of the Chesapeake in three or four hours. They could be equipped with 3-inch guns. The muzzle energy of 100 3-inch guns is equal to the muzzle energy (and therefore destructive power) of about 60,000 soldiers' rifles.

"The size and power of the aeroplanes has already gone far beyond the limits set for its possible development by certain engineers only three years ago. The practical difficulties of making it larger still are quite apparent; yet, nevertheless, no theoretical limits to its size and power have yet been accepted by aeronauts. That the aeroplane is now the best single weapon against the submarine is conceded. That the aeroplane, and especially the battleplane, will rapidly advance in size and power within the coming year and afterwards, is the mature belief of many aeronauts; should we not therefore immediately investigate its capabilities, not only as a scout and accessory, but as a major instrument of warfare?

"I do not suggest the abolition of the soldier and his musket; but neither do I suggest the abolition of the boat pulled by the oars of rowers. I merely suggest that, as the boat pulled by rowers was superseded for large operations by the sailing ships, and as the sailing ship was superceded by the more mobile steamer with broadside guns; and as this type of warship was superceded by the turret ships, and as the turret ship has been expanded into a super-dreadnought, so the soldier and his musket may be superceded for important operations by the immeasurably more powerful and mobile battleplane.

"If so, the more quickly we act, the better. 'Hindenburgh never sleeps.'"

REFORM IN AIR SERVICE CAUSES CHANGES IN FOREIGN GOVERNMENTS

GENERAL LYAUTEY, a new French War Minister, has resigned following disagreements caused essentially by projected reforms in the French air service.

The struggle for aerial supremacy in Europe has been responsible for many changes in the British and French Governments in the past two years. Before that there was an occasional change of subordinate heads of the air service. It will be recalled that the British Assistant Secretary for War, Col. Seeley, was the first to go on account of failure to develop the Royal Flying Corps. His successor, Assistant Secretary Tennant also had to go for failing to work out the necessary reform. Then Lieut. Col. Mervyn O'Gorman, who had for a number of years been the Superintendent of the Royal Aircraft Factory was demoted—his demotion being the result of a nation wide agitation for reform in the administration of the air service, which was the prime factor in also causing a thorough change in the British Government. In other words, when developing the air service was only a measure of preparedness the subordinates were punished for the failures to train a larger number of aviators and get adequate equipment; but when war came and the administration remained sluggish, and the failure to develop the air service endangered the very existance of the nation, which was willing to spend $250,000,000 in twelve months to gain and maintain its supremacy in the air, then the country forced the changing of the entire Cabinet.

In France, Assistant Secretary Besnard was put in charge of aeronautics last year in a position which was virtually the position of an Air Minister. But he found, as the British reformers found, a deeply rooted, selfish bureaucracy, similar to the sluggish, self-seeking British bureaucracy, which opposed practically every suggestion of development in the air service, for no other apparent reason than the fear that with the developments might be put other men in charge.

So Besnard resigned, and General Lyautey has also resigned.

France is due for a house cleaning similar to the house cleaning that resulted in the establishing of the British Air Ministry, which was the first step of the new British administration.

This house cleaning may not be easy but it is expected that it will be easier than the British house cleaning. The latter was a hopeless proposition for a number of years and it required a change of the entire Government administration to do it.

The British experience showed what an amazing power a few retrogressive bureaucrats, using the Government machinery, can have for evil. A very small number of retrogressive bureaucrats who were themselves incapable of developing the air service sought to prevent others from doing it, essentially from fear of losing their positions or fearing reflection on their own actions if they followed lines of progress suggested by those patriotic, far-seeing people who sought to develop a larger and more efficient air service.

In some cases the men were only obsessed with the past limitations of aeroplanes and their minds simply could not accept the progress which had been made in aeronautics. So they restricted its development and application for military purposes. But their obsession was a menace to national safety, and they had to be removed—which was eventually done.

Then there were the crank theorists who spent most of their time trying to disprove that aeroplanes designed and built outside of the Royal Aircraft Factory could be better than the R. A. F. products; and the official scoffers who scoffed at everything that did not emanate from the Royal Aircraft Factory and repressed by suppression all outside efforts to develop a greater air service. To these must be added those misguided individuals who, as the official investigation brought out, actually appropriated ideas submitted to the Royal Aircraft Factory by outsiders.

It had been thought that these evils would disappear when the Royal Aircraft Factory was confined to experimentation and manufacture of spare parts, but they did not disappear, they rather grew worse as the air service extended and the Royal Aircraft Factory employed 3,000 men.

Occasionally the British public and press would express its displeasure at the limitations of the air services and would refuse to accept the impressively phrased reports of officials, which usually praised the departments for what they claimed to constitute "progress"—and then there would be a change in officialdom. Several under secretaries were changed and the head of the Royal Aircraft Factory was removed and finally an Air Board was instituted. The administration of the Royal Flying Corps alone now occupies about 350 offices in London.

The selfish, retrogressive office holders craftily used the entire bureaucratic machinery to oppose the appointment of the first Air Board and succeeded in having the Board shorn of power.

But, as is usually the case with people of this type, their small minds could not grasp the immensity of the situation and realize the necessity of getting and training thousands of aviators and providing them with a sufficient and efficient equipment.

As is usual in such a case, progressive executive officers in both the British Army and Navy, were powerless to stamp out the evil, being unwilling to have quarrels in the bureaus. The bureaucrats operated the government machinery to their advantage and stopped at nothing to suppress and silence their critics. Aeronautics being a new science the superior officers had to rely on different section officers for information. These officers seemed to have formed a clique and they seemed to stop at nothing to carry out their selfish purposes.

They hampered and obstructed every progressive move started outside of their offices and persistently forced on the Royal Flying Corps R. A. F. products quite inferior to machines and motors developed by private firms.

They whitewashed each other and attempted to blacken the character or ridicule any critic that happened to criticise their inaction or inexcusable delays and favoritisms.

But with the tremendous growth forced upon them there came a large number of new officers, including a great many progressive men who soon found out the status of affairs and undertook the work, leaving these selfish officers to their selfishness.

Finally the public and press got tired of excuses and promises, of reports on alleged "superior" technical developments and complaints of "unfounded" charges. These things did not defend the British Islands from Zeppelin attacks, and did not keep the coasts free of submarines and the skies free of German aeroplanes.

The British aeronautic magazines that carried on the propaganda which resulted in the establishing of the new British Air Board deserve much credit.

One magazine in particular, *The Aeroplane,* is to be congratulated. The editor of this magazine worked untiringly for aerial preparedness, carrying a weekly fight against the sluggish Royal Aircraft Factory and the evil of Government construction which prevented Great Britain from getting an adequate air service before the war and urging persistently the establishment of an air ministry.

The bureaucrats fought him in a low, malicious way. They actually resorted to trying to force manufacturers to cut out their advertising from *The Aeroplane,* attempting to bribe manufacturers with orders to carry out their insidious scheme. But *The Aeroplane* published the facts about this plot and the manufacturers' patriotism and manliness balked at being part to such a low scheme, and the result was that *The Aeroplane* received greater support, while the malicious bureaucrats were demoted.

Fair at all times, the editor first tried praising and urging; then he tried to impress upon them that his one interest was only to get the substantial aerial defenses needed in the interest of the country and that he was only too anxious to cooperate with them and help them in every way possible. Finding it impossible to make progress he just did his duty. He rendered Great Britain a great service by continuing his fight in spite of all the discouraging experiences he had.

An Order in Council signed by the King on February 6th sets up the Air Board, which is constituted as follows:

President—The Right Hon. Viscount Cowdray (Minister of the Air).
Parliamentary Secretary—Major J. L. Baird, M. P., C. M. G., D. S. O.
Fifth Sea Lord of the Admiralty—Commodore G. Paine, C. B. (The Admiralty's Air Lord.)
Director-General of Military Aeronautics—Lieut.-General Sir David Henderson, K. C. B.
Controller of Aeronautical Supplies—Mr. William Weir.
Controller of Petrol Engines—Mr. Percy Martin.
Secretary—Sir Paul Harvey, K. C. M. G., C. B.
Assistant Secretary—Mr. H. W. W. McAnally.
Private Secretary to the Parliamentary Secretary—Mr. C. G. Evans.

The constitution makes provision for such additional members as may from time to time be found desirable.

In the event of one or other of the Admiralty, Army Council, Aeronautical Supplies, or Petrol Engine Departments' representatives being unable to attend a meeting of the Board, the department to which he belongs may designate an officer to attend in his place. Members of the Air Board other than those who are appointed in virtue of their offices shall be appointed by the President of Board, and shall hold their appointment at his pleasure.

General Lyautey had decided to amalgamate the various departments of the air services and to place them under one central authority in Paris, under his own control, but with General Guillemin in charge. It was understood that General Guillemin was to eventually have charge of both the Army and the Naval air services. Until that time M. Thomas, the Minister of Munitions, was to continue to control the manufacture and supply of aircraft. Just what happened is not yet known in details. The fact is that General Lyautey has resigned as Secretary of War as a result of disagreements over plans for the development for air services.

This last development and the fact that there is still a feeling that the plan to give Great Britain 20,000 fully equipped aviators is not being developed as fast as it should, and that air raids on Germany are not as numerous as they could be may result in bringing about the appointment of an Allied Air Board. And that may be a great step forward.

THE NEWS OF THE WEEK

Aeronautic Stations to Guard Coast

Washington, D. C.—A joint Army-Navy board is studying the Atlantic and Gulf Coasts preparatory to the establishment of eight aeronautic stations, which besides having two dirigibles and six or eight seaplanes each for aerial patrol work, probably will serve as a base for the new 110-foot coast scout boats of which the Navy will order more than a hundred in a few days. Sixteen dirigibles and a sufficient number of seaplanes have already been contracted for, and officers and men for the air service are being selected to be sent to the station at Pensacola, Fla., for training. A school dirigible for the station is about ready for delivery.

The eight stations will be distributed along the coasts to cover strategic areas to be determined by the board. Each will require six officers and forty men.

The only station site already definitely selected is that at Coco Solo, near Colon, Canal Zone, for which an appropriation of $1,000,000 to establish a joint aviation and submarine base was asked of the last Congress. The project is expected to go through at the coming special session. Funds for the other stations will be asked at that time, but the department has emergency appropriations sufficient to begin the work at once. The dirigibles are to be delivered within four months.

At present no stations for the Pacific Coast are being prepared, although the chain of coast patrol bases will be extended along the entire coast line as rapidly as machines can be procured and men trained.

The immediate scheme requires the training within the next four months of fifty officers and 350 men at Pensacola in handling dirigibles. Crews for the seaplanes are already under training, but their number must be increased largely without delay.

In providing boats to aid in the task of guarding the coasts navy experts would prefer a standard type 130 foot steel boat for patrol and submarine chasing work, but in the interest of speedy construction has determined on the 110 foot craft, with wooden hulls, so that builders of wooden boats can share in the work. Later orders will be placed for some small submarine chasers ranging from fifty to eighty-five feet in length.

Fort Totten May Be Plane Station

New York.—Colonel William G. Haan, commandant of Fort Totten, is a member of a joint naval and military board named by the War Department to consider sites for aeronautic stations along the Atlantic coast for the protection of the coast cities.

A large number of hydro-aeroplanes are now being built by the government and will be used jointly by the army and navy. It is said that Fort Totten may be chosen as the station for the hydro-aeroplanes that are to protect New York City.

Foreign Branches for U. S. Rubber

New York City.—Chas. F. Guest, who has represented the United States Rubber Co. in Mexico for a number of years, has sailed for Manila, where he will open a new branch for the company. The new office, of which he will be manager, will handle a large part of the Oriental trade of the company, formerly in the hands of the San Francisco office. Another new branch will shortly be opened by J. A. McKenzie in Australia to handle the growing U. S. Rubber business there.

Aeroplane Factory for Davenport

Davenport, Iowa, will have an aeroplane factory in operation by March 26, manufacturing military tractors, both land and water machines.

Mr. Billy Cook, a pilot with great experience, has been retained as head of the construction work. The backers of the company plan to have an up-to-date flying school near the factory, training pupils on machines built at the factory. They report that they have twenty-five applications at the present time. Besides acting as head of the construction, Pilot Cook will be instructor in the school.

Stewart-Warner Election

Chicago, Ill.—At a recent election of the Stewart-Warner Speedometer Corp., Chicago, the following officers were named: President, C. B. Smith; Chairman of the Board, L. H. LaChance; Vice-Presidents, V. R. Bucklin, W. J. Zucker, T. T. Sullivan; Secretary, W. J. Zucker; Treasurer, T. T. Sullivan.

Flying Routes to Be Mapped

New York.—Plans by which the United States will be surveyed to establish aeroplane routes and landing stations, both for military and civilian aviators, are being worked out at the Government Flying School, at Mineola, L. I. These plans have already progressed so far that the regular officers of the school and a committee of the reserve aero squadron have begun to arrange for suitable landing stations at various distances, even as far away as Philadelphia, and to mark these stations in such a way that they will be easily distinguishable from the air.

The scheme as projected by Capt. Joseph E. Carberry, commandant of the school, is expected to enlist not only the aid of all aero clubs and the War Department, but the Coast and Geodetic and the Geological Surveys.

Capt. Carberry and the fliers of the school have carried on a number of experiments and as a result within a short time the big field at Mineola is to be marked with a big star of canvas, the points of which will be twenty-five feet in diameter. Other fields at Oyster Bay, Port Washington and other points will be similarly marked. In addition, a symbol will be attached to each marker which will denote the character of the field of landing, its proximity to repair stations and even to hospitals in case of accident. By this means an aviator, looking for a place to land, can pick out a field which suits his needs.

It has been found that the tent hangars of the field at Fort Sill, Okla., are visible eighteen miles away at a height of 6,000 feet.

In addition to charting out the countryside, the reserve fliers of the Hempstead Plains School are planning a course of work under conditions closely simulating actual warfare. Maps of the countryside are being made from aeroplanes, and more than 200 topographic photographs have been filed away this year. These photographic maps have a great advantage over the ordinary scale maps in that they show detailed conditions of the terrain below and the exact location of even the smallest buildings and landmarks.

The camera is to take another important part in training the civilian aviators. It is to be used in target practice. With a camera mounted on his machine instead of a machine gun, but operated by regular gun sights and trigger pull, the student aviator will soon be sent up with orders to "bring down" a certain machine designated as the enemy. The scheme works on the natural presumption that if a flier can aim well enough to get a bullseye through his camera he could do it with a rapid fire gun.

800 People See Franco-American

Eight hundred representative people attended the latest of the remarkable entertainments which Mr. Alan R. Hawley, the energetic president of the Aero Club of America, conducts so successfully in the beautiful ball room of the Automobile Club of America.

The motion pictures included films of the work of the American Ambulance, but the popular film was the one showing the Franco-American Flying Corps. The corps were shown in flight and in their camp. The famous American aviators, William Thaw, Norman Prince, Elliott Cowdin, Kiffin Rockwell, C. C. Johnson, Lufbery, Chapman, and others were shown, and received a rousing reception.

The speakers included Henry A. Wise Wood, Lieut. George H. Roeder, of the American Ambulance Corps in France, and Miss Mary Lawton, who recited stirring poems.

Mr. Henry A. Wise Wood announced an important plan to build a million tons of "Ford" merchantmen advanced by F. Huntington Clark, a mining engineer, of 30 Broad Street, to break the German high seas barrier. Mr. Clark's plan received the indorsement of Rear Admiral Bradley N. Fiske (retired).

Wooden, motor-driven, little merchantmen, low in the water, quick on their heels and without smoke or tall masts to betray them at a distance, are the craft recommended by Mr. Clark. They would average 185 feet long, 34 feet beam, 18-foot draught, with a cargo capacity of 1,000 tons and a speed of 14 knots. Mr. Clark estimated that the capacity of the yards the first year would be 1,000,000 tons, and Mr. Wood suggested last night that with the adoption of Ford methods of standardization the capacity of the yards would be virtually unlimited.

No expensive plants would be required; a planing mill, a couple of saws and such accessible timber supply as exists in the Beaumont district of Texas and on the Pacific Coast are the only requisites. Steel demand, congestion of rolling mills and shipyards would not affect the new industry. Three vessels a year could be built on the same ways, it is said.

The ships would cost about $100,000 apiece. The operating cost would be about $4,000 a month. The gross returns at the present rate would be from $15,000 to $20,000 a month.

Such ships, even when picked up by a submarine, would present a much more difficult mark for the torpedo. They would be small and of slight draft and would be able to dodge quickly. They might almost be considered too small to warrant the discharge of an expensive torpedo. If the missile did hit its mark the loss in life and property would be comparatively small.

Mr. Clark would arm each boat with two guns. He points out that a pair of guns is a pair of guns, whether mounted on a ponderous 10,000-ton liner or a nimble 1,000-ton jitney of the seas. One would be as dangerous to the U-boat as the other. Owing to the low visibility of the smaller craft Mr. Clark figures that their entry would necessitate three times as many submarines to maintain the blockade, and he is confident that the little boats could be turned out faster than they could be sent to the bottom.

If the United States were involved in war, he pointed out, such an auxiliary fleet would be of immense value for patrol purposes and as mine sweepers.

Those present were the members and their friends of the Automobile Club of America, the Aero Club of America and the Motor Boat Club of America, under whose joint auspices the weekly entertainments are held.

Aeroplanes Rushed to Essington Base

Philadelphia, Pa.—Within a few hours after the announcement that the United States War Department had decided to take over the Philadelphia School of Aviation at Essington for the purpose of converting it into a base for air squadrons to co-operate with the Atlantic reserve fleet at League Island supplies from the Government began arriving at Essington.

Nor did the War Department lose any time in placing an officer at the head of the school, for it was announced that Captain William Ocker, who recently flew from Long Island to Washington, carrying Congressman Bleakley, of Franklin, Pa., from this city to the capital, would take active charge at once. Captain Ocker is an officer in the United States Reserve Corps, having recently been promoted from the rank of sergeant.

About $2,000 worth of cable wire, several typewriters and other office equipment have already arrived at the school. Bills of lading, received by Walter E. Johnson, who has been chief instructor, show that four aeroplanes, two motortrucks, two motorcycles, two motorboats—capable of making forty-five miles an hour—and considerable machine shop equipment are already on their way to Essington.

The Government, having decided to maintain a base for an aerial fleet and a school for the training of reserve air squadrons at Essington, will spare neither money nor effort for its development. It is said that the War Department is prepared to spend $250,000 to make it an efficient arm of the United States fighting forces.

New Connecticut Aviation Field

Greens Farms, Conn.—The new aviation park, which is situated just west of New Creek at Burial Hill Park, Greens Farms, is the eastern end of Sherwood's Island, and it appears to be most admirably situated for this purpose. It has a fine stretch of sandy beach, with New Creek to be improved for a harbor and the new Burial Hill Park road, which the town built last year, for an approach. It has access to the new water main on Beachside avenue and also electric light connection at that point.

To Test Packard Aero Engine

Detroit, Mich.—Within the next two weeks the Packard Motor Car Co. will install its aeroplane engine in an aeroplane and test it by flight at Joy Field.

Goodyear Adopts Metric System

Akron, Ohio.—The metric system of weights and measures will be introduced in the plant of the Goodyear Tire and Rubber Company. This means that in all weighing system, in all its mould designs and in all of its machinery designed in the plant the company will use the metric system.

The completion of this move will extend over a period of months. Draftsmen are already provided with metric scales and drawings are being arranged along this line.

The pusher biplane of the General Aeroplane Co., Detroit.

To Aid Our Aviators Fighting for France

New York.—An entertainment, followed by a ball, was held in the Waldorf-Astoria March 16 to augment the fund which has been raised for the relief of the American Aviation Corps and the Ambulance Francaise de Pierrefonds, a hospital in the little village of Pierrefonds, near the firing line, to which soldiers too seriously wounded to permit of their removal to the base hospital, are taken for emergency treatment.

Many prominent artists, among them Marie Dressler, who directed the entertainment; George M. Cohan, Trixie Friganza, Gertrude Kingston, Georgia Caine and Adelaide and Hughes, volunteered their services, and Conrad's Orchestra furnished the dance music.

Three members of the American Aviation Corps, Robert Rockwell, Frederick Zinn and Elliot Cowdin, who have distinguished themselves by their exploits in France, among the guests, and bluejackets from the U. S. battleship Arizona acted as ushers.

Indiana Guardsmen for Aviation Corps

Indianapolis, Ind.—Three Indiana guardsmen will depart soon for San Diego, Cal., where they will be trained in flying to become aviators for the Indiana National Guard. The men pioneers in the field, so far as the Hoosier guard is concerned, will form the nucleus of an aviation corps for the I. N. G.

The three are First Lieutenant Ernest Clark of Terre Haute, first battalion of the Second infantry, Sergeant Major Frederick I. Elgin, also of the Second infantry and another first lieutenant of the Second infantry, whose name is withheld by request. The guardsmen took examinations in aviation while they were on the border.

Bock Bearing in Standard Parts

Cleveland, Ohio.—Control of the Bock Bearing Co., Toledo, Ohio, has been secured by the Standard Parts Co. of Cleveland, thus placing the latter company in a position to make the entire running gear. William E. Bock, president of the Bock Company, will continue to head its affairs and will be a director of the Standard Company. It is planned to turn out 10,000 bearings a day.

J. G. Utz has been appointed chief engineer for the Standard Parts Co. He has been with the Perfection Spring Co., now a Standard Parts subsidiary, for five years. E. W. Dunston has been appointed chief engineer for the spring division, and R. A. Townsend has become chief metallurgist in charge of the spring division laboratories.

Army Balloonists Fight Snowstorm

Gibes, Mo.—Three United States Army balloonists left here by train for Omaha March 18 after a struggle for five hours in a snowstorm at an elevation of 10,000 feet.

The balloon was piloted by A. Leo Stevens, chief instructor of the United States balloon corps, at Fort Crook, and also carried Captain H. J. B. McElgin and Lieutenant L. C. Davidson. They left Omaha Saturday morning and landed here at half-past four in the afternoon.

On reaching an altitude of about ten thousand feet they encountered a severe snowstorm which cut off all view below and prevented them from attempting a landing for five hours.

Detroit, Aero Club Elects Officers

Detroit.—The Aero Club of Detroit held its annual luncheon and meeting recently, electing a Board of Governors.

The newly elected governors are: A. Verville, of the General Aeroplane Co.; G. W. Dunham, consulting engineer; W. B. Stout, aeroplane engineer of the Packard Motor Car Co.; K. C. Zimmerschied, of the General Motors Co.; D. McCall White, engineer of the Cadillac Motor Car Co.; R. O. Gill, manufacturer and manager of the Saxon Motor Car Co., and R. W. Judson, vice-president of the Continental Motors Co.

At a recent meeting of the Board of Governors, the following officers were elected: President, Sidney D. Waldon; vice-president, Henry B. Joy; vice-president, Fred M. Alger; treasurer, R. D. Chapin, and secretary, Mason P. Rumney.

Aviator Finds Lost Engineers

Miami, Fla.—After being lost in the Everglades for more than a month, three New York engineers were found by Phil. Rader, the instructor at the Curtiss Aviation School, here.

They started from Miami about five weeks ago on an engineering trip, with food to last them but three weeks, and only by carefully conserving it have they made it last. The search for the men lasted almost three weeks and brought in the native Florida residents, Seminole Indians, and the aviators from the Curtiss School.

Aerial Reserve in Training

Washington, D. C.—The first quota of twenty-three men from the enlisted Signal Reserve Corps has arrived at three aviation schools on the Atlantic seaboard to undergo six months' training. Seven will be trained at the Curtiss School at Newport News, Va.; seven at the Curtiss School at Miami, Fla., and nine at the Signal Corps at Mineola, L. I.

New Hydrodynamics Text Book

N. W. Akimoff is completing a text book on Applied Hydrodynamics, meant mostly for Aeronautic engineers. The book will be of the same general character and meant for the same class of readers as his recent book, "Lagrange's Equations." Mr. Akimoff would be glad to receive suggestions on the part of all engineers interested in the technical end of Aeronautics as to topics which they would be especially anxious to see worked out in detail.

Curtiss News

Some very interesting information has recently been furnished by officers of the United States Army relative to flights made during the past few months by Curtiss aeroplanes on the Mexican border. For about six weeks last summer mail aeroplanes left Columbus, New Mexico, every other day for Gen. Pershing's headquarters at Colonia, Dublan, Mexico, about 115 miles south. A return trip was made the next day.

All first class mail for troops carried, and on some trips, all classes of mail up to 300 pounds in weight. Bulk of mail, not weight, was usually the limiting factor.

All planes flying from one station to another carried mail, averaging about two mail-carrying flights per week for about six months. Average distance mail carried each flight about 160 miles.

In addition to mail all sorts of articles have been carried, as the following list taken at random shows:

	Lbs.
Pilot and passenger.	
Military equipment consisting of arms, food, water, tools, first aid pack, sleeping bags	140
Mail, three bags	130
Two spare magnetos	40
Butter	30
Bedding	12
Candy	4
Jam	10
Total	366

Not a single piece of mail was lost.

Average flying time, between Columbus and Dublan, about one hour and fifteen minutes. Greatest flying time between above points, two hours.

On February 13, 1917, the Curtiss speed boat Miss Miami, powered with a Curtiss 12-cylinder V-4 aeronautical motor, made an unofficial world's record by traveling sixty-five miles per hour over a measured course at Miami, Fla.

Army and Navy News

Capt. John C. P. Bartholf, junior military aviator, S. C., now on leave, is relieved from further duty at San Diego, Cal., and will proceed to Hampton, Va., for duty as supply officer at Experimental Station.

Capt. William C. Ocker, Aviation Section, S.O.R.C., is relieved from duty in the office of the Chief Signal Officer and will proceed to Essington, Pa., for the purpose of organizing a temporary aviation station for the training of personnel for a proposed aero squadron to be located near Philadelphia (March 12, War D.).

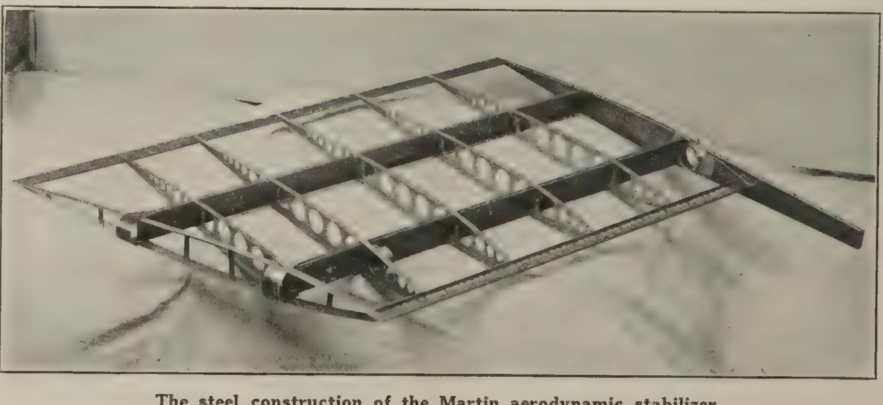
Sergt. 1st Class Roland G. Blake, S.C., Fort Myer, Va., to Miami, Fla., for duty at the Curtiss Aviation School. (March 13, War D.)

Sergts. William A. Hoeveler, Jr., and Joe G. Trees, of the S.E.R.C., Key West Barracks, Fla., to active duty at the Curtiss Aviation School, Miami, Fla., March 12, 1917. (March 9, War D.)

Sergt. Samuel P. Mandell, 2d, of the S.E.R.C., Fort Monroe, Va., to active duty in the Aviation Section, with station at the Curtiss Aviation School, Newport News, Va., March 12, 1917. (March 9, War D.)

Sergts. James W. Watts and Edwin M. Welch, of the S.E.R.C., Fort Monroe, Va., are assigned to active duty in the Aviation Section, with station at the Curtiss Aviation School, Newport News, Va., March 12, 1917. (March 9, War D.)

Sergts. Arthur L. Richmond, Frederick H. Harvey, John Mitchell and Hamilton Coolidge, of the S.E.R.C, Key West Barracks, Fla., are assigned to active duty in the Aviation Section, with station at the Curtiss Aviation



The steel construction of the Martin aerodynamic stabilizer.

School, Miami, Fla., March 12, 1917. (March 9, War D.)

Sergt. Lloyd L. Harvey, of the S.E.R.C., Fort Monroe, Va., to active duty in Aviation School at the Curtiss Aviation School, Newport News, Va., March 12, 1917. (March 9, War D.)

Sergts. Randolph G. Page and Gilmore L. Tilbrook, of the S.E.R.C, Fort Monroe, Va., are assigned to active duty in the Aviation Section at the Curtiss Aviation School, Newport News, Va., March 12, 1917. (March 9, War D.)

Sergt. Howard N. Murphy, S.E.R.C., Fort Monroe, Va., is assigned to active duty in the Aviation Section, with station at Curtiss Aviation School, Newport News, Va., March 8, 1917. (March 7, War D.)

Sergt. Dunn K. Steele, of the S.E.R.C., now on duty at the Curtiss Aviation School, Newport News, Va., to Miami, Fla., for duty at the Curtiss Aviation School at that place. (March 9, War D.)

The make-up of the joint Army and Navy Board shows the importance of the plans that are under way. It includes, besides General Squier, Major Stanley O. Embick, U. S. A., assistant to the Chief of Coast Artillery; Major Dan T. Moore, General Staff, Army War College; and from the Navy, Capt. Hugh Rodman, of the Navy General Board; Capt. Josiah S. McKean, assistant for material in the office of the Chief of Naval Operations; and Capt. George R. Marvell, in charge of naval districts in the same office. The latter is representing the Secretary of the Navy on the board. At the same time that this board is meeting in Washington a commission composed of Capt. Shepler W. Fitz Gerald, Signal Corps, U. S. A., an officer of Coast Artillery and two from the Navy, are traveling along the coast inspecting possible sites for the joint bases.

A special meeting of the National Advisory Committee will be held March 22. Army and Navy officials and representatives of the manufacturing end of the industry will meet on that date in the Munsey Building, Washington, D. C., for the sole purpose of expediting the production of aeroplanes.

Goodyear Purchases Fabric Mills

Akron, O.—The proceeds of the recent stock issue of the Goodyear Tire & Rubber Co. will be used in part for the financing of a deal whereby the Goodyear company buys fabric mills in Connecticut. The fabric end of the business will be handled by a new corporation recently formed under the name of the Goodyear Tire & Fabric Co.

The Late Tex Millman

Peter Carl Millman, better known as Tex Millman, a prominent aviator and instructor to the First Aero Corps, died on March 18 of pneumonia at 101 Jerusalem avenue, Hempstead, L. I. He became a flier five years ago when he was only seventeen years old. He entered the employ of one of the companies demonstrating aeroplanes near Hempstead as a mechanic's helper. Within a short time he give up that calling for the pilot's seat, and since then he had driven almost every make of machine and had flown in all parts of the country. He was known as a spectacular flier, but he never had an accident.

A year ago Millman entered the Government service as instructor to the First Aero Corps. Five months ago he married Miss Mary Schulz, of Hempstead.

A squadron of twelve aeroplanes of the First Corps flew over his grave in Westbury Cemetery just after he was buried and their pilots dropped flowers as a mark of respect. There was also laid on his grave a large floral piece, a tribute from the 200 employes at the aviation camp in Hempstead.

DETAILS OF THE RUMPLER BIPLANE

Following the description of the 1916 type Rumpler biplane, which appeared last week in Aerial Age, some of the prominent details are illustrated below. The drawings are from *L'Aerophile*.

In the upper main plane the wing spars are of ash, and in the lower main plane they are of spruce. Flanges are of pitch pine, and webs of mahogany. The trailing edges are formed of steel tube.

Interplane struts are of tubular steel of streamline section. Near the ends they taper sharply and terminate in a ball which is slotted to receive an eyebolt which runs vertically through the wing spar. Struts are so pivoted on the eyebolt that when the cable is loosened they can pivot sideways and be slipped out from between the planes. Anchorage for the bracing cables consists of a hollow dome-shaped steel shell slotted in places to receive the turnbuckles.

Vibration and friction is prevented where the bracing cables cross by the employment of a sheet metal clip composed of two parts held together with a rivet, one part clamping around each of the cables.

Attachment between the wing spars and the fuselage is quickly made. The spar end is provided with a duraluminin fitting, the hooked end of which fits into a cup-like receptacle which is incorporated in the longeron fitting. A single bolt holds the wing-fitting to the fuselage fitting. The drift cable turnbuckle is attached to this fitting.

Cables are provided with fittings which permit them to be separated for dismantling the machine. These connections are of the button-and-groove type, which, when the cable is slackened, can be easily detached.

THE STAGGER AND CAMBER OF BIPLANE WINGS*

By PAUL A. G. KAUFFMANN, E. S. A.

TESTS to determine the influence of longitudinally staggering the lifting surfaces of a biplane have been made at the Auteuil Laboratory with wings having the Dorand camber; it was found that when the upper surface of the biplane is staggered forward to the extent of 1/2.25th of the distance between it and the lower surface, this gap being 9-10ths of the chord of the surfaces, an increase of the lift-coefficient K_{ya} † of from 6 to 10 per cent. results; but the ratio $\frac{K_{xa}}{K_{ya}}$ remains the same, as is also the maximum value of R_{ya}. No great practical advantage is therefore, in this case obtained from the stagger.

M. Eiffel had previously tested a biplane consisting of two surfaces 90 × 15 cm., of circular curvature, with a camber of 1/13.5th of the chord, and a gap of 4-3rds of the chord; the top surface was staggered forward to an amount equal to its chord in one experiment and to half the chord in another; the ratio $\frac{K_{xa}}{K_{ya}}$ became better than that of a no-stagger biplane only when the value of the lift co-efficient, K_{ya}, was greater than 0.066, and then the improvement increased with the stagger; the maximum value of K_{ya} was improved by 5 per cent. in the case of the stagger equal to ½ the chord and by 10 per cent in that of the stagger equal to the chord of the surface.

The National Physical Laboratory has found that with a Blériot curvature, of aspect-ratio 4, the lift co-efficient was increased from 5 to 6 per cent, and the lift-to-drift-ratio improved by from 1 to 4 per cent. when the upper surface was staggered forward to an amount equal to 1/2.5th of the gap, which itself was equal to the chord of the surfaces.

The Göttingen Laboratory has carried out a number of experiments by first placing the upper surface forward of the lower one, then exactly above, and finally behind it. In each case a series of experiments were made when the lower surface had, with reference to the upper surface, inclinations of + 2°, 0° and — 2° respectively.

The amount of longitudinal stagger was + ⅔, 0, — ⅔rds of the gap which was equal to the chord, the curvature having a camber 1/20th of the chord in the case of the lower surface and of 1/14th of the chord in that of the upper surface.

(Fig 6.)

When the longitudinal stagger is 0, no improvement was found by giving a greater incident to the lower surface; full-sized machines, on the other hand, have nearly all a better lift to drift ratio by the adoption of this device. (Fig. 4.)

No improvement was again obtained when the upper surface was staggered forward, the angles of incidence being the same: the lift co-efficient only increases 8 per cent. (Fig. 5.) When the upper surface is placed forward at an incidence greater than that of the lower surface, there is gain only from a given value of lift co-efficient equal to 0.055, this result being contrary to what seems to be the case when a study is made of the Sopwith, Nieuport, Deutsche, Flugzenwerke, Luftverein Gesellshaft, etc., biplanes. Besides, in this case, Gottingen finds that the maximum lift co-efficient is 9 per cent. greater than in the no-stagger biplane and 4 per cent. than that if the monoplane, a result which, at first sight, might appear astonishing. (See Fig. 6.)

Being given that the various experimental results relating to the simple longitudinal stagger and to angular longitudinal stagger do not agree with one another, it can be assumed that, to a great degree, the results obtained differ from one another on account of differences in the curvature of the surfaces. Besides, one should always consider a biplane as forming an aerodynamical whole which cannot be reduced to a simpler expression; it is therefore necessary to study separately each side of each of the surfaces.

In accordance with the lastest Auteuil experiments, the top side of the upper surface of a biplane is not influenced by the lower wing; it can, therefore, be looked upon as the top surface of a monoplane wing and be given a curvature similar to that employed for monoplanes—that is, one with a camber lying between 1/10th and ⅛th of the chord.

The under side of the upper wing and the top side of the lower wing influence each other; this interference may be considered as acting in two ways: it diminishes K_{ya} and increases $\frac{K_{xa}}{K_{ya}}$; it is this increase of $\frac{K_{xa}}{K_{ya}}$ that it is most important to suppress, while a small decrease of K_{ya} may perfectly be tolerated at small inclinations. If K_{xa} diminishes at the same time and in a similar manner, one could even say that this decrease is advantageous; in fact, at small angles a decrease of K_{ya} for a same angle and for the same ratio $\frac{K_{xa}}{K_{ya}}$ gives a more flexible polar curve (Fig. 7), since the maximum $\frac{K_{xa}}{K_{ya}}$ takes place in general from 2° to 5° at a lift co-efficient comprised between 0.02 and 0.04; and at great inclinations we have seen that Göttingen has shown an increase of K_{ya} *minimum*, and of the ratio $\frac{K_{ya}}{K_{xa}}$ for a K_{ya} greater than 0.05 (for a biplane with the upper surface forward, with — 2°).

With a view to reducing the interference of the under side of the top surface and top side of the under surface, one can try to give more or less camber to each of the sides facing each other; in order to achieve this purpose it should be remembered that the air arriving on a convex portion (back of wind, for instance), increases its speed; whilst on a concave portion, as that of the under side of a wing, the speed is much reduced.

In consequence, if a great camber is given to the under side of the upper wing, a considerable mass of air will be stopped by that camber, and the horizontal speed of the mass of air will be reduced, and a downward speed communicated to it. This mass of air will then considerably interfere with the top side of the lower wing; on the other hand, if the under surface of the upper wing is flat, or, still better, cambered in a direction inverse to the usual one (convex instead of concave), such an arrangement would facilitate the flow of air, and would even enable it to acquire additional speed; it would therefore increase the efficiency of the top side of the lower surface. It is true that, in the latter case, a certain amount of lift on the under side of the upper surface is lost: K_{ya} is reduced, but $\frac{K_{xa}}{K_{ya}}$ remains the same. (See Technical Report of Advisory Committee for Aeronautics, 1911-12.)

---

* Translated from *L'Aérophile*, September, 1916. The author of the article, M. Kauffmann, is an engineer of the Ecole Supérieure d'Aéronautique, founded and ably conducted by Commandant Roche, who, when the Aeronautical Institute of Great Britain was founded, very kindly accepted to be on its Advisory Board, thereby giving it the benefit of his valuable experience.

† The symbol K_{ya} is adopted to denote the vertical or Y-component of the air co-efficient when the inclination of the surface is a. Similarly K_{xa} is used to denote the vertical or X-component for inclination a, and R_{ya} denote the lift.

THE LOWER SURFACE.

The top side of the upper surface, not being influenced, there is no reason to give it less curvature than that of a monoplane wing; on the contrary, having an angle of attack 2° greater than the upper surface, one can give it a greater camber.

The under side of the lower wing, not being influenced, can have the same camber as the under side of a monoplane wing.

The Caudron biplane belongs to a class of aeroplanes in which the flexible upper wing, not being interfered with, effaces itself in the wind to a greater degree than its lower wing, whose R_{ya} is reduced by the upper surface. M. Caudron has made experiments in which the angle of attack of its lower surface was increased by 1°, 2°, and 3° respectively; he has found that in none of these arrangements was there any advantage; from 4° the ratio $\frac{K_{xa}}{K_{ya}}$ was not so good. In the case of the Caudron the angular stagger was, to a certain degree, automatic.

M. Bréguet, in his former machines, with very flexible wings having one single spar, was, in order to have the least possible drift, obliged to give a greater incidence to the upper wing; the automatic angular stagger was in that case too large, on account of the extreme flexibility of the wings.

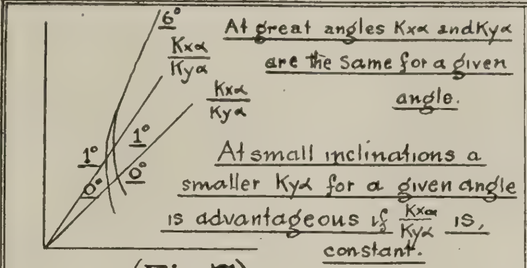
The new Bréguet machines, with rigid wings and two spars, have, like the majority of existing biplanes, more incidence at the lower wing.

When flexible wings are employed, it is therefore necessary to take into account the degree of flexibility of the wings, and the disturbance which the flexibility brings into the incidence of the various surfaces, once the machine is in flight.

One can, therefore, conclude as follows:—

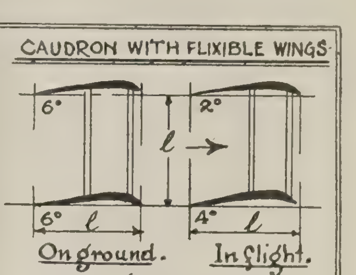
Give to the top side of the upper surface and to the under side of the lower surface the current monoplane curvature; to the top side of the under surface, a curvature somewhat larger than that of the top side of the upper surface; and, especially, to the under side of the upper surface no curvature or a slightly convex one; the lower surface lagging behind the upper surface, it should have a slightly larger angle of incidence.

With flexible wings, the angular stagger of construction should be small, zero, or negative, according as the wings are rigid, flexible, or very flexible.

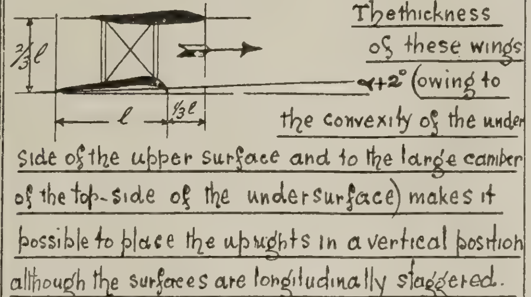


6°
$\frac{K_{x\alpha}}{K_{y\alpha}}$
$\frac{K_{x\alpha}}{K_{y\alpha}}$
1°
1°
0°
6°
At great angles $K_{x\alpha}$ and $K_{y\alpha}$ are the same for a given angle.
At small inclinations a smaller $K_{y\alpha}$ for a given angle is advantageous if $\frac{K_{x\alpha}}{K_{y\alpha}}$ is, constant.

(Fig. 7.)

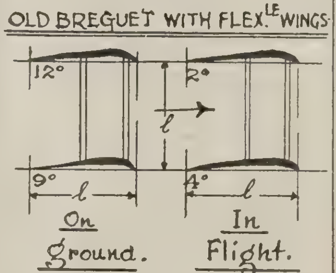


(Fig 9.)



$\frac{2}{3}l$
l
$\frac{1}{3}l$
The thickness of these wings
$\alpha+2°$ (owing to the convexity of the under side of the upper surface and to the large camber of the top-side of the undersurface) makes it possible to place the uprights in a vertical position although the surfaces are longitudinally staggered.

(Fig. 8.)



(Fig. 10.)

THE WOODWARD AERO NAVIGATOR

PATENTS have been granted to Mr. Charles D. Woodward, of Providence, R. I., for an invention whereby aero-navigation by using the shadows from the sun is made possible and extremely simple by a mechanical device. The device is really a mechanical sun dial, which, by its own clock works and other devices for adjustment to circumstances, points out and automatically corrects the points of the compass geographically, and not magnetically.

In the embodiment of the invention, use is made of two sets of clock hands and faces, one of which keeps Greenwich mean time and the other is adapted to be set to the local apparent time of the place of observation.

In connection with such clock mechanism, use is made of a style and of a graduated shadow-disk marked in the sun's degrees and also with points of the compass and connected with the clock mechanism for rotation in correspondence or agreement with the relative angular motion of the earth and sun and adapted to be set with reference to the sun's degrees, represented by the time difference.

In connection with the mechanism, use may be made of an index wheel that is of service in setting the shadow disk. The disk is constructed of frosted glass, so that its markings can be read from the bottom.

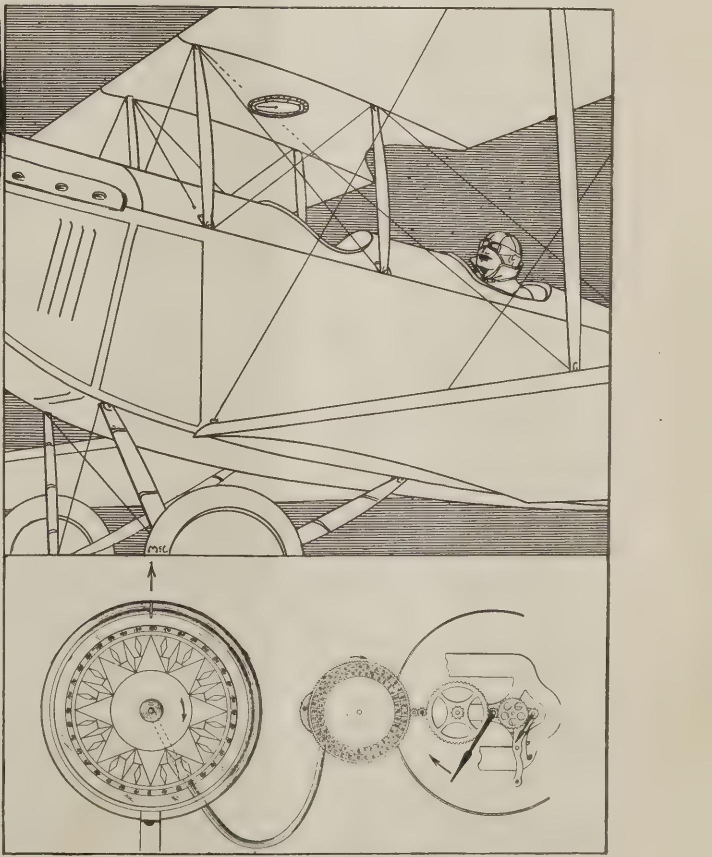
The lubber line in connection with the centre of the disk indicated the fore and aft direction. The clock hands are driven from the same clock mechanism as is also the disk by means of a shaft, which may be flexible.

The disk is arranged above the aviator so that he can conveniently read it from the bottom. If the aeroplane is at rest, for example, on the ground in a certain locality and is facing north, although that fact may not be known to the aviator, then at noon in that locality the shadow cast by the style on the disk will lie due north and south, so that the shadow will indicate 180 on the disk and also the marking indicating north.

The aviator by reference to the shadow reads the marking for north and ascertains that he is facing north. As time goes on the disk is turned clock-wise at the rate of one revolution in twenty-four hours and its degree corresponds with the sun's degree, so that if after some time has elapsed the shadow be again referred to it will still indicate the north marking on the disk, since that marking has traveled through the same number of degrees as indicated by the relative travel of the sun and earth

It is evident that if the aeroplane instead of remaining still had turned around more or less, it would have turned the disk and the lubber marking collectively, but not in respect to each other, so that in these circumstances reference to the shadow and the marking which it indicates on the disk afford means for ascertaining the direction in which the aeroplane is pointed, and of course generally indicated the points of the compass.

After the apparatus has been thus set it will continue to run, and an observation of the shadow in respect to the disk affords means for determining direction, as has been indicated, and also means for determining the exact geographical position of the aeroplane because it gives the sun's true bearings.



The Woodward Aero Navigator.

FOREIGN NEWS

AUSTRIA-HUNGARY

"Automobile and aeroplane motor manufacturers in Hungary have formed an organization as a subdivision of the National Union of Hungarian Manufacturers," says a consular report. "Prior to the war the automobile industry was not flourishing, but war orders have greatly strengthened it, and the association just formed is for the purpose of protecting the interests of the manufacturers and for dealing with questions that will come up after the war, also during the war, to represent the manufacturers at the Ministry of War.

"Among the questions to be considered for business after the war will be import duties on automobiles, an agreement between factories as to types of cars to be manufactured, and the disposition of the large number of cars that have been used in the war and that will be on the market afterwood. It is possible that American methods will be followed and quantity production of motor cars begun."

FRANCE

PARIS, March 17.—Capt. Georges Guynemer demonstrated again yesterday his claim to be the world's premier aviator by dashing three German machines to earth in three combats in one hour.

This intrepid, slightly built youth, who travels in the fastest man-made vehicle ever constructed, took the air after several weeks of resting and immediately apprised the enemy of his presence.

Climbing to a tremendous altitude, he set sail for the inside of the German lines, as it is useless for French aviators to await the Germans, who never leave the protection of their Krupp anti-aircraft guns.

When well inside the German lines Guynemer darted after a big two-gun Fokker, keeping above it, so that the German machine guns were useless, and sniping off both its wings with his own mitrailleuse. After the Fokker was smashed, he turned the nose of his craft upward, his terrific momentum defying gravitation, and bagged the second German machine from below in his own private fashion—shooting through the floor of the enemy machine. This endangers him, as the other aeroplane is likely to fall upon him, but Guynemer has escaped so far.

The third German was destroyed when he tried to lure Guynemer down within range of the anti-aircraft guns. The Frenchman pretended to start into the trap, then suddenly quickened his speed and shot the enemy machine to pieces before the latter had time to turn and fire back.

Guynemer has now brought down thirty-four machines and easily the foremost military aviator in France. Only twenty-two years old and making a meteoric rise from a simple soldier two years ago to the rank of Captain in the Flying Corps, he has won the Legion of Honor, the Military Medal, the Croix de Guerre and every other honor which an admiring nation can bestow.

GREAT BRITAIN

It has been officially announced that the following is the composition of the British Air Board:—

President, the Rt. Hon. Viscount Cowdray.
Parliamentary Secretary, Major J. L. Baird M.P., C.M.G., D.S.O.
Fifth Sea Lord of the Admiralty, Commodore G. Paine, C.B., M.V.O.
Director-General of Military Aeronautics, Lieut.-General Sir David Henderson, K.C.B..
Controller of Aeronautical Supplies, William Weir.
Controller of Petrol Engines, Percy Martin.
Secretary, Sir Paul Harvey, K.C.M.G., C.B.
Assistant Secretary, H. W. W. McAnally.
Private Secretary to the Parliamentary Secretary, G. G. Evans.

The formation of the new Air Board is authorized by an Order in Council published in the "Gazette" of Feburary 6th, as follows:—

1. The Air Board shall, until it is by Order in Council otherwise directed, consist, in addition to the President, as follows:—
   (a) A Parliamentary Secretary of the Board;
   (b) The Lord Commissioner of the Admiralty who is charged with the direction of the Naval Air Services;
   (c) The member of the Army Council who is charged with the direction of Military Aeronautics;
   (d) The Controller of Aeronautical Supplies and the Controller of the Petrol Engine Department, of the Ministry of Munitions;
   (e) Additional members as may from time to time be found desirable.
2. In the event of one or other of the officers named under the letters (b), (c), (d) above being unable to attend a meeting of the Board, the Department to which he belongs may designate an officer to attend in his place.
3. Members of the Air Board other than those who are appointed in virtue of the holding of certain offices shall be appointed by the President of the Board.
4. Members of the Air Board appointed in virtue of the holding of certain offices shall continue to be members of the Board so long as they hold those offices. Members appointed otherwise than as aforesaid shall hold their appointments at the pleasure of the President of the Board.
5. This Order may be cited as the Air Board Order, 1917.

LONDON, March 13.—James Ian Macpherson, Parliamentary Secretary to the Under Secretary of State for War, replying in the House of Commons today to a question voicing recent criticisms of the British Air service and suggesting that the British no longer maintained the mastery of the air on the western front, said:

"We are satisfied with our best type of flying machines at the front. Some machines which are not up to standard are being replaced as rapidly as possible."

The average weekly air casualties for the last six weeks, Mr. Macpherson said, had been: Killed, 7.6; wounded, 8.3, and missing, 4.2.

"The situation in the air," the Parliamentary Secretary continued, has not yet been decided. During the Winter all the belligerents endeavored to improve and to increase their air services. With the advent of good weather severe contests must be expected before definite superiority is achieved.

"In one respect the British always have been superior to the Germans, namely, in the amount of work performed by the flying corps for the army. The situation is very similar to that obtaining in the same period last year, when the Germans, rested and reinforced after the Winter, put up serious opposition, and only after severe fighting was the British superiority established.

"This year the German concentration appears to be on the front of the British. The move probably is connected with the German retirement. Reinforcements and replacements are continually being sent to the front, and there is every reason for hope that the British again will assert their superiority."

LONDON, March 17.—Another Zeppelin raid on London, the first since November 27, ended last night in disaster for the German airships. Apparently while the raiders were returning to their base one of them, flying at a height of more than two miles over the Somme battlefield in France, was sighted by anti-aircraft batteries and was brought down to earth with a shock that split it in two.

The attack on London, details of which are withheld, caused little or no excitement, even among returning theatregoers. Favored by a dark and moonless night, the Zeppelins first appeared over the south-eastern counties of England, where twenty-seven bombs are reported to have been dropped on the rural districts, without inflicting much damage.

The raiders are believed to have reached London just before midnight.

SIGHTED NEAR THE SOMME

Returning homeward, the great airships passed fairly close to Paris about 4:15 this morning. At that time firemen went through the streets of the French capital extinguishing lights and warning the residents by blowing sirens. At 6 o'clock it was announced that all danger was over.

Shortly before dawn French gunners near Compiegne, forty-five miles northeast of Paris and almost on the Somme battle line, sighted one of the Zeppelins. The first shots from the anti-aircraft batteries reached the airship, which was nearly three miles up. It suddenly burst into flames, remained poised in the air a moment and then crashed to earth. Striking a garden wall, it broke in two, a mass of wreckage from which the burned bodies of thirty of the crew were afterward extricated.

As the airship fell, leaving a trail of fire from the blazing fragments of the envelope, several of the crew jumped out of the gondolas, all of them being crushed to death as they struck the earth. The remaining bombs in the Zeppelin were thrown out as the airship descended, most of them striking in the open fields and failing to explode. The Zeppelin was later identified as the L-39.

Airmen returning from France report that the Germans are using new methods of combating the British airmen. Hitherto it has been possible for the British aviators to patrol over the important German positions by making squadron flights, the Germans using scattering anti-aircraft fire.

Now the Germans concentrate their anti-aircraft guns on given areas, forcing the British aviators to go through a withering fire if they wish to reconnoitre the positions.

Lieutenant Vernon C. Blythe, of the Royal Flying Corps, has received the Croix de Guerre for valorous action on the Western front.

Lest a world satiated with daring deeds and military crosses should yawn and refuse to read past the first paragraph, let it be added at once that Mrs. Vernon Castle made this announcement.

Lieutenant Blythe is known in a land that pays more attention to dancing than to aeroplanes as Vernon Castle. According to his wife, the little cross on his breast means that he has brought to earth two German fighters.

"Vernon had three weeks' leave in London," Mrs. Castle said. "We were together all the time, but we didn't dance. Officers are not allowed to dance in England any more. He looked well and happy, and he is back on the French front now, winning more crosses, I hope."

HOLLAND

AMSTERDAM, March 15.—A German aeroplane which flew over Sluis was shot at and hit by Dutch troops who were manoeuvring in the neighborhood, according to the Handelsblad.

The aviator was wounded and compelled to descend in Dutch territory, but before he could be overtaken by the Dutch soldiers, he restarted his machine and flew three hundred metres over the border into Belgium. German troops hurried to his rescue and he was carried away by Red Cross attendants.

JAPAN

From "Japan Times" February 8

Major Isobe who is attached to the French aviation corps is now taking an active part in aerial warfare somewhere near the Verdun theatre of war, according to his recent letters. After one year's volunteer service at the front, Major Isobe returned some time ago to Paris to take a rest-cure, but being restored to health and strength he again proceeded to the front on January 13. He is one of the veteran Japanese flyers and is said to have a good command of looping the loop which he has learned in France.

From "Japan Times" February 10

Dr. Kishi's new aeroplane No. 3 "Tsurugi" which has been completed recently will be piloted by Lieutenant Inouye on February 10 and 11. The flights will be made at the reclaimed ground at Susaki, Fukagawa. The new machine is the third aeroplane constructed by Dr. Kishi who is an earnest student of aeronautics, all his machines have been made of Japanese materials entirely.

Flights for army officers have been arranged for Saturday and Sunday from Tokorozawa, past Hachioji in the suburbs of Tokyo, over Obosatsutoge (a mountain, 2,000 metres above the sea level) and Mt. Enzan to the city of Kofu, in Yamanashi prefecture. Thence to Lake Suwa in Nagano prefecture. Two Morris-Farman aeroplanes will be used. The chosen pilots are Lieuts. Makabe and Takikawa. They will start from Tokorozawa at 8:30 on Saturday morning for Kofu, where they will make a stop at the parade ground of the Kofu regiment. After an hour's rest the two flight officers plan to set out for Suwa in Nagano prefecture. On the next day they are expected to fly above the frozen surface of Lake Suwa.

On the return journey, it has been arranged that Lieuts. Nagasawa and Nakada will relieve their comrades and attempt a non-stop flight to Tokorozawa.

Kite Flying at the Drexel Aerological Station, by the Aerological Division, Wm. R. Blair in Charge

A photograph showing the relative location of the Drexel farm buildings and the ground used as a kite field will be shown in a forthcoming issue of AERIAL AGE. The lease for the property went into effect a short time ago, and the work of installation of the kite flying and other equipment was immediately begun. The granary was modified to accommodate the carpenter shop, a small testing room for calibrating and testing meteorographs, a small machine shop for repairs to apparatus and machinery, a power plant room containing the gasoline engine, generator, and switchboard for the distribution of electric current, and storage room for kites.

The carpenter shop is completely equipped for the building and repair of kites. The power plant consists of a 250-volt, 5-kilowatt generator, directly connected with a 4-cylinder gasoline engine. The power generated is used to operate the kite reel, also the saw table of the carpenter shop, the lathes and drill press of the machine shop, and for lighting the shops and the reel house when kite flights are being made at night.

The wind tower, instrument shelter, rain and snow gages were completely installed and observations begun. The concrete foundations for the track of the reel house could not be laid until 1915. The superstructure of the reel house, the installation of the power plant and all wiring were completed and the first free-air record obtained on October 22, 1915. Daily free-air observations were begun December 1, 1915, twenty-eight observations having been obtained during October and November, 1915.

The track and rollers for the reel house, all equipment for the carpenter and machine shops, kites and power reel, calibrating apparatus, wind tower, and other equipment for the observation of surface meteorological conditions, horse and wagon, and furniture for offices and quarters were shipped to the Drexel station from Mount Weather, Va., in the autumn of 1914 and later.

The Drexel station is 396 meters above sea level, 41° 20′ north latitude and 96° 16′ west longitude. The kite field is comparatively level, extreme variations in its level being less than 3 meters. The station is about 32 kilometers west of Omaha; 8 kilometers from Elkhorn, Neb., the nearest station on the Union Pacific Railroad, and an equal distance from Washington, Neb., the nearest station on the Chicago & Northwestern Railroad. Mail reaches the station daily by rural free delivery from Washington, Neb. Freight, express and telegrams are best sent via Elkhorn, Neb.

Photographs showing the farm buildings and their environment, the beginning of a kite flight, and a near view of the reel house showing the reel, will appear in a forthcoming issue. The apparatus for turning the house on its track, and the instrument shelter in which the kite meteorograph is exposed, along with standard instruments before and after each flight. The reel house fronts away from the wind during a flight, consequently the instrument shelter is so located as to be well in the surface wind. An open roof above the shelter protects it from heat that might be reflected to it by the side of the reel house near which it is exposed. A small reading telescope mounted in the reel house enables the observer to read conveniently the instruments exposed in the shelter. It shows the variable speed motor by which the reel is driven and, in part, the method of insulating the reel from the reel house and from the power system. This insulation enables the observer to read the difference in electric potential between the kite and the earth at any time. The motor switch, starting and reversing box, clutch lever, speed variation, brakes, dynamometer, and line meter are all brought to the right side of the reel and may be conveniently operated or read by the operator without change of position. The drum of this wheel has a capacity of about 14 kilometers of piano-wire line.

The country surrounding the Drexel Aerological Station is level or somewhat rolling, nowhere deeply cut by creeks or rivers. Practically all land in this vicinity is under cultivation. Kites that break away are quickly found and returned to the station. A preliminary study of the data being obtained indicates that valuable results for dynamic meteorology are likely to accrue from free-air observation at this and prospective stations located in the open plains of the Middle West.

The Aero Science Club of America

Before the issue of this edition of AERIAL AGE the Aero Science Club of America will have held its first banquet in commemoration of the progress made by the club. There is no doubt but that the affair will be a success; a large number of tickets having been disposed of to a large majority of out of town members as well as to resident members. Every effort was made by the committees in charge to insure the success of the banquet.

The model aeroplane season is about to begin and many contests are planned to take place although no definite dates have been arranged. The banquet marks the beginning of activities on the part of the Aero Science Club and there is every indication that the coming year will not have passed without the establishment of many new records.

Y. M. C. A. Model Aeroplane Activities

Under date of March 13th, George A. Cavanagh delivered a lecture on "The Advantages of Model Flying" before a large gathering of young men associated with the Eastern District Y. M. C. A. of Brooklyn. By the use of motion pictures and slides the speaker was enabled to clearly demonstrate the wonderful progress of aeronautics both in this country and abroad. The young men present displayed considerable interest in the subject and at the conclusion of the lecture many expressed their desire of becoming members of the Model Aero Club of the Y. M. C. A. Mr. Cavanagh also spoke before the members of the Model Aero Club of the Y. M. C. A.

Model Aero Club Formed in Ithaca High School

At the meeting of the newly formed Aero Club at the High School, officers were elected as follows: President, Frederick Wilcox; vice president, George Vivian; secretary, C. Osborn Macky; treasurer, Lawrence Doll.

The Aero Club is co-operating with the Thomas Brothers Aeroplane Company and plans are under way to arrange a series of talks by Mr. Thomas and members of the company for the benefit of the club. Mr. Lyke, who is chairman of the club and who is also connected with the industrial arts department of the High School, will take the members of the club through the Thomas factory in the near future.

Contests are to be held in the High School gymnasium. The winners will challenge the aero clubs of other cities. Any one in the High School above the eighth grade interested in aerial work will be welcomed into the club.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

The Seidlitz Five-Stroke Engine

By GERALD DE LETTGO WOOD, in *Flight*

Those of you who went to a decent school, and have forgotten Ovid, will recall the story of Capaneus, the noble but plucky Argive, son of Hipponous and Astinome, and husband to Evadne. When he went to the war he had the temerity to declare that he would take Thebes in spite of Jupiter. Such impiety could only be rewarded by a thunderbolt; but we are told that the body of Campaneus was burned separately from others, and his wife threw herself on the burning pile to mingle her ashes with his.

As to whether Popaufkwick, the eminent Greenland municipal engineer, ever studied Latin we do not know, or does it greatly matter, but that some such idea as that with which the above story ends was present to his mind was evident. Confronted by the problem of designing an engine for the unique machine by which his dear friend, Dr. Chef, expected to reach the Pole, he saw at once for so noble a work it was essential that he should start *ab initio* and, throwing all accented principles to the winds, conceive something entirely original. As one of the three men in the world who had solved the insurmountable difficulties of using quicksilver for drop-forgings, he decided that the engine must have bearings of this type, rabbit lined. (*We fail to see where there was any trouble in this matter, for Greenland is near the Bearing Sea. After looking up our map of the world, we have decided that the joke is rather far-fetched.—Ed.*)

Having proceeded thus far, it became apparent that he should think of the fuel which should be used, and at once, in view of the coldness of the atmosphere in which the engines would have to work, he discarded any and every form of heat engine. Gasoline and steam were, of course, not to be thought of as they had been used before. How he solved the problem is a story which should be entrusted to an abler pen than that of such a humble scribe as the writer, for it is an epic in itself.

One fine afternoon, while indulging in his customary stroll after his matutinal meal, his eyes wandered from the etheral dome of heaven to the snowy mantel which enveloped the whole landscape. As he strolled, he found himself repeating, "Blue and white, blue and white," and at the twentieth repetition he cried, "Ah," in Esquimaux. The natural phenomena spreading itself around had quickened within his brain the germ of an idea. Popaufkwick at once bethought of that excellent hydragogue cathartic named after a little village in Bohemia. His new engine would be of the effervescent or bubbling type.

Vir sapit qui pauca loquitor

It will at once be recognized that the Pole being a fixture it was not likely to move, and *per se* there was no hurry. Why not, therefore, have a slow-running engine? On returning to his office the remaining details were quickly thought out. So far he had not come across a five-stroke cycle engine, *ergo,* the new engine must operate on the five-stroke cycle. It may be as well, before proceeding further, to enumerate the successive phases of the cycle. The cylinder being oscillating, as the piston goes downwards and the cylinder being inclined to one side, the Esquimauchanic in charge administers a blue packet; then on the piston coming up and the cylinder being diverted in the opposite direction, a white packet, according to directions, is added. Now, as the piston approaches the top of its stroke a valve opens, whereupon a spray of fine ammonia mingles the two powders and the resultant release of gas forces the piston downwards. So far we have traced the working of the engine through three successive strokes of the cycle; the fourth stroke is easy—it is none other than exhaust—but of the nature of the fifth, which is essentially in effect a double stroke, I cannot, for obvious reasons, divulge any further particulars. The process of reversing is delightfully simple; all that is necessary is for the Esquimauchanic to forget the scriptural injunction not to let his right hand know what his left hand doeth, and reverse the order of the packets, when the engine will naturally proceed as desired. Beyond stating that the shafts are made of cold drawn walrus tusks there remains very little more to be said about the engine.

(*To be continued indefinitely* [*perhaps.*—Ed.])

Our Own Specifications

(*Editor's Note.*—We found this article on the desk of one of our proofreaders. He had just finished tabulating the specifications and requirements for dirigibles of eighteen countries, and we fear that his mind was affected from wading through six hundred pages of technical data.)

1. All bids must be in the day before they are due or the bidder may have to pay some penalty for being late.
2. Kindly send on no drawings ahead of time because we are liable to get them mixed up.
3. After bids are awarded to the winning firm, eight of our inspectors, who know absolutely nothing about balloons, will be sent to each factory to see that no materials not up to our standards are used. These inspectors will have the final say in all disputes. If the contractor objects to their decision he can write to us, but absolutely no attention will be paid to the letter.
4. After the dirigibles are constructed we *may* buy them, but we guarantee nothing.
5. Nothing in paragraph 4 is to be construed as a contract.
6. If the finished machine weighs more than we think it should, we retain the option of, 1, refusing to accept the machine; 2, taking it but not paying for it. (In most cases the latter method will be followed.)
7. Nothing in paragraph 6 is to be construed as a contract.
8. For every day in advance of the stipulated time that the machine is completed the contractor will have our heartfelt thanks, but we will exact a penalty of one hundred dollars a day for each day beyond the specified time.
9. The successful bidder must agree to split fifty-fifty with the inspectors.
10. However, we reserve the right to change our mind at any time and stop work on the machines in which instance the contractor will be thanked for his pains.
11. Nothing in any of the above paragraphs is to be construed as a contract.

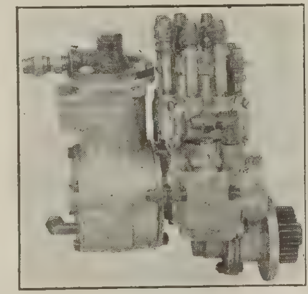
Starts High Powered Engines Cold on Low Pressure



Supplied to the U. S. Navy

THE marked efficiency of the Christensen Self Starter is perhaps best suggested by the results of a test on a Hall-Scott Motor made at the Standard Aero Mfg. plant in Plainfield, N. J. There on a tank of air of 250 pounds pressure, 28 complete starts were made without recharging the tank, and the last start was made on the low pressure of 100 pounds.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

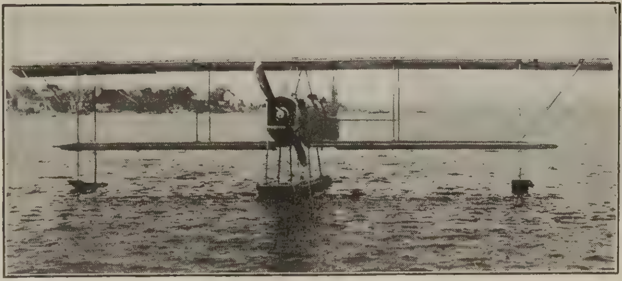
AN EXPERIENCED AVIATOR WITH LONG experience as instructor, on pushers and tractors and monoplanes, wishes connection with reliable firm as instructor or demonstrator. Correspondence confidential. Address Box 123, Aerial Age, 280 Madison Ave., New York City.

FOR SALE: TWO BENOIST FLYING BOATS with one hundred H.P. motor. One Curtiss type biplane machine in fine condition. Thirty one hundred for entire equipment. Lorain Aviation Company, Lorain, Ohio.

WANTED AT ONCE, COPIES OF EARLY issues of Flying Magazine. Address Box 117, Aerial Age, 280 Madison Avenue, New York City. Particularly Volume 1, Nos. 11 and 12, Vol. 2, Nos. 1 and 9, and Vol. 3, Nos. 6 and 7.



Burgess Training Hydroairplane

Among the many models of Airplanes, Seaplanes and Flying Boats produced by this company the new "U" type Hydroairplane meets a very pressing need—an efficient, well-balanced flying machine of conventional type and low power for militia training purposes.

The Massachusetts Naval Militia has the first one now in service.

Standard Deperdussin control in duplicate; Curtiss OXX-2 motor; simple float; light, sturdy construction; large speed range (forty to sixty-eight miles per hour); are characteristics necessary to the hard service required for training purposes.

Hydroplanes and pontoons designed and manufactured for airplanes of every type, including Curtiss, Sturtevant and other makers.

Designers and constructors for the U. S. Army and Navy and British Admiralty.

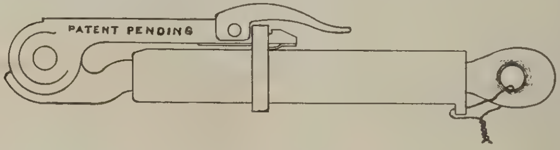
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

Quotations and deliveries on request.

Above All:--Strength

The knowledge of strength engenders confidence, and the direct result of confidence is the will and power to excel. No matter from what angle we consider the aeroplane and the dirigible, STRENGTH is of paramount importance, completely overshadowing other characteristics of the machines of the air.

It is but common knowledge that a chain is as strong as its weakest link, and it is not stretching the point to say that the aeroplane is efficient, strong and sturdy as its fittings and special parts.

STRENGTH, however, is not mere bulk, brute power, or weight. Anyone could build strong fittings,—but the fittings would undoubtedly be far too heavy for the modern machine. Strength, then, in the aeroplane, must be the result of scientific research, absolutely the finest of materials, and *hairline precision*.

ACCURACY can result only from long experience at a task, and conscientious adherence to the scrupulous performance of it.

SERVICE is obtained in direct proportion to the knowledge, skill, materials,—and *conscience* put into the manufacture of a product.

The Erie Specialty Company is now supplying Screw Machine Products and Aluminum Castings to the leading aeroplane companies:—the aeroplane companies which desire the finest fittings and special parts that modern science and skill can produce.

Every part that leaves the factory of the Erie Specialty Company is tried, tested, and proved perfect.

We shall be glad to hear from those manufacturers of aircraft whose desire is for Screw Machine Products and Aluminum Castings which are accurate, strong, and efficient. Tell us your requirements and we will submit estimates and early delivery dates.

Battleplane with Lewis Machine Gun mounted on bow of car. This plane was the first of its kind in the world

"In my private opinion the Lewis Machine Gun is the best light type gun yet developed for troops in the field."

Major-General LEONARD WOOD,
Commander of the Department of the East.

General Wood stated he "favored having . . . a reserve supply of 25,000 machine guns as in the end one in ten men will carry a 26 lb. machine gun as he now carries a rifle."

Statement made by Major General Leonard Wood testifying before the Military Committee of the House of Representatives reported in New York World, January 28th, 1916.

AVIATION TRAINING

THE CURTISS School of Aviation will give training this winter, in Florida, to those civilians who may be accepted by the Aviation Section, U. S. A., upon their having made application for enlistment in the Aviation Reserve Corps. Applicants must be between twenty-one and twenty-seven years of age, possess good health, character and college education or equivalent. Tuition will be paid by the Government.

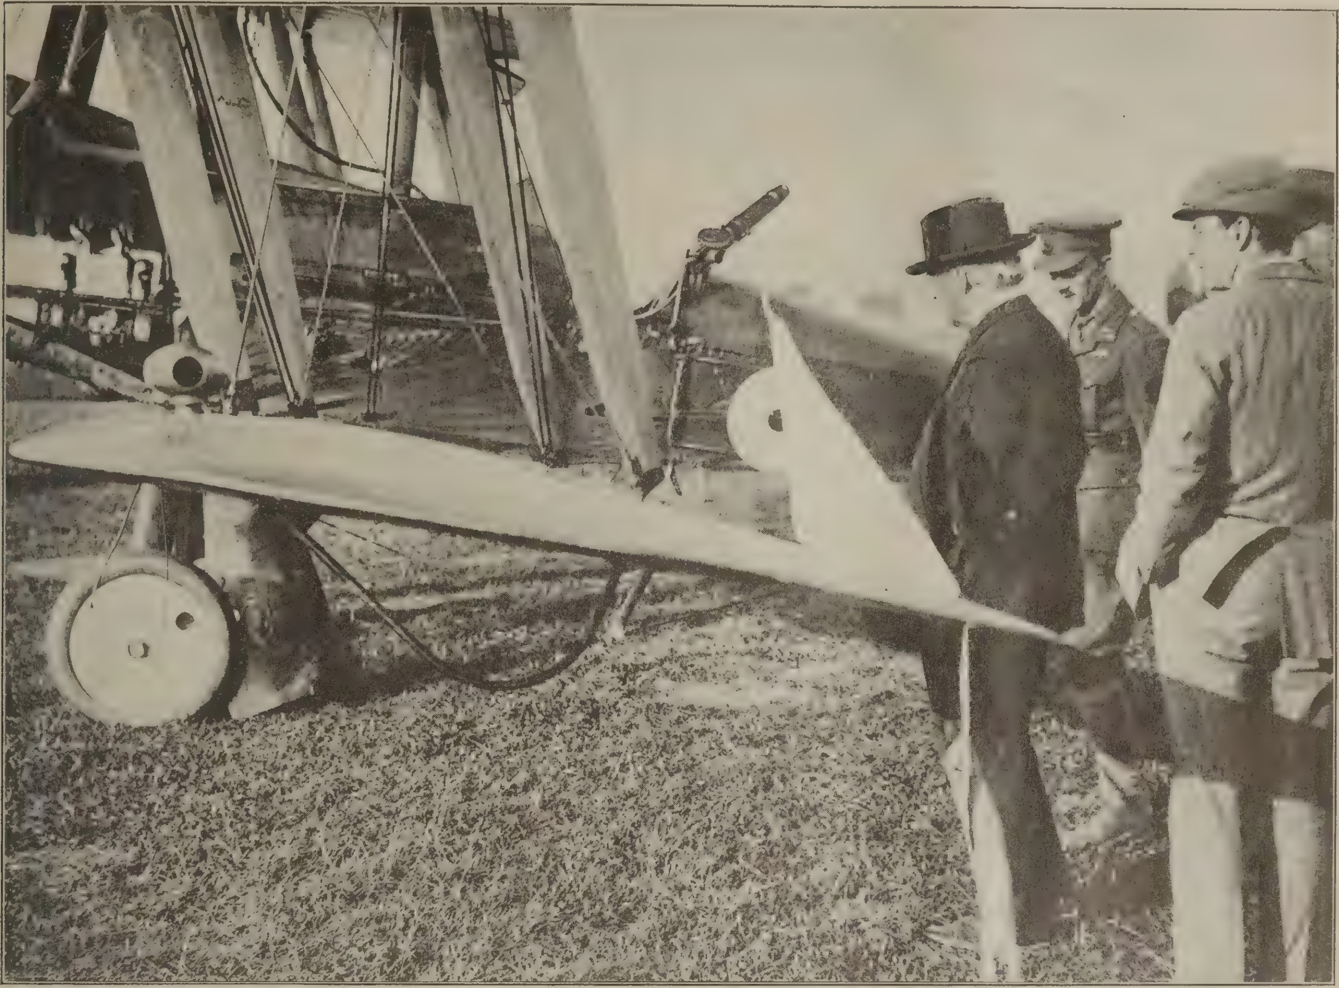
CURTISS AEROPLANE & MOTOR CORPORATION

BUFFALO, N. Y.



Mr. Asquith inspecting a 'plane equipped with Lewis Gun which has just returned from a flight

"VIRTUALLY all our aeroplanes are armed with Lewis Guns and of the seven Zeppelins we have accounted for, six were brought down by the Lewis Gun."

The above statement of Mr. Sidney Brooks, English Publicist, was printed in the Philadelphia Public Ledger, February 14th, 1917.

This indicates the almost universal use of the Lewis Gun in aeroplanes in use by the Allied armies, due to the light weight of this arm, its mobility, and its versatility.

Over 40,000 Lewis Automatic Machine Guns are in use in the First Line of Offense of the Allied armies.

VOL. V NEW YORK, APRIL 2, 1917 No. 3

4,000 AEROPLANES FOR ARMY AND NAVY BY 1919 IS PLAN OF NATIONAL ADVISORY COMMITTEE ON AERONAUTICS

ARRANGEMENTS for speeding up the plans of the Government for aerial preparedness were discussed at an all-day conference March 22, between representatives of the aircraft manufacturers of the country, the Executive Committee of the National Advisory Committee for Aeronautics and the Aero Club of America. In an address to those representing the Government and the industry attending the conference, which was held behind closed doors, Dr. Charles D. Walcott, Director of the Smithsonian Institution and Chairman of the National Advisory Committee, after reviewing the work done by the army, the navy, and the aircraft industry in the last year, said that the country had scarcely made a beginning toward real aerial preparedness.

Dr. Walcott asserted that the annual requirements of aeroplanes for the army and navy would be 2,000 aeroplanes and 2,000 military and naval aviators, and that 2,000 additional machines and 400 aviators would be needed for training pilots. The industry in its present state, he said, was unable to meet the country's requirements without great expansion.

The principal development of the meeting was the appointment of a special committee of seven to arrange details of speeding up production of aircraft and the temporary standardization of types required. This committee will consist of four members of the National Advisory Committee for Aeronautics and three representatives of the Aircraft Manufacturers' Association. Their names are withheld for the present.

"The aeronautic industry's inability to meet the needs of the Government," said Dr. Walcott in his address to the manufacturers, "is in itself only another example of the fact that though millions may be available for a specific purpose in time of great need, no amount of money will buy time. Even the most generous appropriations do not open up the years that have passed and enable us to carefully lay the foundations of a great industry and a great aerial arm through the education of engineers, manufacturers, teachers, and all of the wide variety of personnel required. An aeronautical engineer, for instance, does not step full-fledged into being, but is the result of years of patient study of and experience with aircraft. Such an evolution can only be accomplished with time.

"At the present time there are not more than twelve aeroplane manufacturing organizations in the United States with the necessary engineering and manufacturing experience and facilities to justify Government business. The first conclusion to be arrived at is, therefore, that these factories must be encouraged to expand as rapidly as possible to reach a capacity of planes per year that might be considered as our reasonable needs.

"There are many estimates of our reasonable needs, and the one herewith presented has been prepared after conferences with as many men as could be reached who have experience or judgment qualifying them to express an opinion, and after obtaining as much data as possible from Europe.

"Tentative estimate of annual requirements of aeroplanes (assumed to be possible of accomplishment in 1919):

"Attachment to an army of 1,000,000 men, 1,000 planes and 1,000 aviators.

"Attached to our fleet at sea, 200 planes and 200 aviators.

"For harbor and seaport defense, 800 planes and 800 aviators.

"Total, 2,000 planes and 2,000 aviators.

"For training pilots, (worn out or broken), 2,000 planes and 400 aviators.

"Total, 4,000 planes and 2,400 aviators."

A special committee of the Aero Club of America which went to Washington on March 21st at the invitation of the National Advisory Committee on Aeronautics, advised the Government that more than 200 wealthy men in and near New York were anxious to buy their own seaplanes and to undergo training, without compensation, if they could be taught by naval aviation instructors. This means an offer of $2,000,000 from patriotic New Yorkers, the average cost of seaplanes being $10,000 each.

Representative Murray Hulbert, Henry Woodhouse, a member of the Board of Governors, and Augustus Post, Assistant Secretary of the club, were the committeemen. They conferred with General Squier, Chief Signal Officer of the army; Dr. S. W. Stratton, Director of the Bureau of Standards; Dr. Charles D. Walcott, Secretary of the Smithsonian Institution, and Lieut Commander John H. Towers, U. S. N.

PLANS MATURING FOR AVIATION SECTION IN THIRD NAVAL DISTRICT

PLANS for the organization of a substantial naval flying reserve force for the aerial defenses of the Third Naval District have been developed by the Advisory Committee on Aeronautics appointed to co-operate with Rear Admiral Nathaniel R. Usher, the Commandant of the Third Naval District, and are rapidly being put into effect.

The committee, which was appointed on March 2, at the request of the naval authorities, and is co-operating with the other committees working in organizing the naval reserves of the Third Naval District, includes:

Chairman, nominated by Rear Admiral Usher: Mr. Alan R. Hawley, President of the Aero Club of America, member, Aerial Coast Patrol Commission, Mayor Mitchel's Committee of 1,000; Chairman, Aeronautic Committee, National Security League.

Operations and Coordination: Rear Admiral Robert E. Peary, Chairman of the National Aerial Coast Patrol Commission, member of the Board of Governors, Aero Club of America, and other national organizations; Eugene S. Willard, Member, Committee on Naval Aeronautics, Aero Club of America; New York Yacht Club, member Board of Governors and Chairman New York State Enrollment Committee, Naval Training Association of the U. S.; Member, Executive Committee, Power Craft Association.

Enrollments: F. Trubee Davison, son of H. P. Davison, member of the firm of J. P. Morgan & Company, Organizer, Volunteer Aerial Coast Patrol Unit No. 1; Lewis S. Thompson, Training Camp for College Men.

Flying Equipment: Henry Woodhouse, Member, Board of Governors, Aero Club of America, National Aerial Coast Patrol Commission; Chairman, Committee on Aeronautics, National Institute of Efficiency; member, Mayor Mitchel's Committee of One Thousand on National Defense, National Security League, etc.; F. Trubee Davison, W. Earl Dodge, Howard S. Borden.

Torpedoplanes, Aerial Guns and Explosives: Rear Admiral Bradley A. Fiske, retired, President Naval Institute of the United States; member of Committee on Naval Aeronautics, Aero Club of America, etc.

Naval Anti-Aircraft Defenses: Eugene S. Willard, member of Aero Club of America, N. Y. Yacht Club, and chairman, New York State Enrollment Committee, Naval Training Association of the U. S., etc.; Schuyler Skaats Wheeler, President of the Crocker-Wheeler Co., inventor of numerous important electrical and mechanical devices, Vice President, Automobile Club of America, who is developing several aeronautic devices of importance; Captain Robert A. Bartlett, who was captain of Peary's ship, the "Roosevelt," in the North Pole Expedition, and of the "Karluk" on Stefansson's Expedition. (Captain Bartlett has been preparing an Arctic expedition which is to include aeroplanes in its equipment, but is now putting his efforts in developing the aerial defenses.)—Henry Woodhouse.

Communications: (Radio, signaling, etc.); John Hays Hammond, Jr., member, Board of Governors, Aero Club of America; Conference Committee on National Preparedness, Treasurer and Chairman, Institute of Radio Engineers; Lawrence B. Sperry, aviator and inventor, expert in instruments for signaling and aerial navigation, William Dubillier.

Observation Balloons: Rear Admiral William N. Little, retired, member of numerous organizations.

Instruction: Robert A. Lovett, son of Judge Robert Lovett, President of the Union Pacific R. R., member of Volunteer Aerial Coast Patrol Unit No. 1; organizer of Aerial Coast Patrol Unit No. 2; F. C. G. Eden, who is in charge of the Dodge Aviation Training Camp for college men.

Aviation Training Camps: Lewis S. Thompson, in charge of the aviation training camps of Volunteer Aerial Coast Patrol Unit No. 1; W. Earl Dodge, founder of the Dodge Aviation.

Secretary of the Committee: Henry Woodhouse.

In its second report to Rear Admiral Usher, Mr. Alan R. Hawley, the Chairman of the Committee, summarizes the work of the Committee as follows:

(1) The Committee has already received a large number of applications for training from men who would like to join the Naval Reserve Flying Corps, and has taken up with the Navy Department the matter of establishing an aeronautic station in or near New York where owners of hydroaeroplanes and flying boats can put up their seaplanes and train under the auspices of naval aviators and those who enlist in the Naval Reserve Flying Corps can take their training.

(2) A representation from the Committee went to Washington on March 21st and 22d and saw the naval authorities regarding the possibilities of establishing the naval aeronautic station in New York. The matter is being considered by the authorities. The Committee in urging that a naval aeronautic station be established in New York assured the authorities that, if necessary, the Committee will secure a suitable place for the station and will also secure all the personnel needed to run the station under the direction of the naval authorities.

(3) There are a number of owners of flying boats and people who would buy hydroaeroplanes and flying boats for their own training as well as for the use of the Naval Reserve Flying Corps, but the general feeling is that there should be a station where the machines could be put up and which would be an aviation training camp.

(4) In anticipation of getting such a station, whether established by the Navy Department or by civilians, and so as to have an experienced naval man to supervise the training of the reserves and the experiments, the Aero Club of America has paid the expenses of sending Rear Admiral William N. Little, retired, to the United States Navy Aeronautic Station at Pensacola to familiarize himself with the administration and general work of the station.

(5) Rear Admiral Bradley A. Fiske, who is chairman of the Sub-committee on Torpedoplanes, Aerial Guns and Explosives, is supervising the developing of the small torpedo to be launched from seaplanes, the Aero Club of America financing the experiments. The Committee sees prospects of obtaining revolutionary results, the torpedoes promising to be of great efficiency, notwithstanding their small size.

(6) Rear Admiral Fiske has reported to the Committee that upon consideration of the subject of preventing the landing of an invading force on our shores he finds that 100 battleplanes, equipped with three-inch guns, would afford the defensive strength of about 60,000 rifles. Shots from three-inch guns could disable and sink transports and destroyers, and the tremendous speed and mobility of the battleplanes would make it possible for 100 such machines to protect the entire coast from New York to the Chesapeake. Needless to add, the 100 battleplanes and trained personnel to operate them would be obtained in a fraction of the time required to get, train and equip 60,000 infantrymen.

(7) Within a few days every member of the Committee will get printed detailed information of exactly how different branches of the naval aernouatic service operate, and a definition of the different service which aircraft can render as auxiliaries of the Navy and naval reserve.

The Advisory Committee on Aeronautics holds periodical conferences with the Advisory Board, which coordinates the activities of the various Committees appointed to assist Rear Admiral Usher in the organization and equipment of the Naval Reserves. The Advisory Board is composed of Messrs. Arthur Curtiss James, W. Butler Duncan, Alfred R. Whitney, Jr. Aviators, balloonists, students and mechanics wishing to join the Militia should apply to Mr. Alan R. Hawley, Chairman Advisory Committee on Aeronautics, 297 Madison Avenue, New York.

PROMINENT MEN TRAINING FOR THE AERIAL COAST PATROL

Twenty-nine members of the Aerial Coast Patrol, including the original twelve members of Volunteer Aerial Coast Patrol Unit No. 1, who gained national prominence for their pioneer work in connection with the "Mosquito Fleet" manœuvres last September, have already left the Yale University and started for the aviation training camp at West Palm Beach, Florida, on Wednesday, March 28th, having received official orders from Secretary Daniels to proceed there to train.

All Yale men, these twenty-nine members of the Aerial Coast Patrol, represent some of the most prominent families in the United States. Their names are as follows: F. Trubee Davison and Harry P. Davison, Jr., sons of Henry P. Davison, member of the firm of J. P. Morgan & Co.; Robert A. Lovett, son of Judge Robert Lovett, President of the Union Pacific R. R.; Albert J. Ditman, Charles Wiman, Artemus L. Gates, Allen Ames, John V. Farwell, John Vorys, Earl Gould, Wellesly Laud-Brown, Reginald G. Coombe, Oliver B. James, G. Franklin Lawrence, William Rockefeller, Frederick Beach, Kenneth Smith, Kenneth McKleish, Curtis Read, Bartow Read, David Ingalls, A. D. Sturtevant, William Thompson, Frank Lynch, Graham Brush, Henry Landon, Samuel S. Walker, Charles Stewart, Archie McIlwaine.

This is one of the results of the patriotic work of Volunteer Unit No. 1, which was organized with the assistance of Mrs. H. P. Davison and Messrs. John Hays Hammond, Jr., Rear Admiral Robert E. Peary, Alan R. Hawley and Henry Woodhouse. Mrs. Davison, realizing the necessity of preparing her sons for an emergency, gave thorough study to the different branches of the service from the standpoint of combined efficiency and safety, and found that aviation afforded the greatest opportunity for efficiency, while at the same time being thoroughly safe.

As Earl Kitchener has said, an aviator is worth an Army Corps. General Pershing has also found that an aviator is worth a cavalry division. The work of the Aerial Coast Patrol, consisting entirely of training naval aviators, the members of the unit will form a valuable reserve for the Navy to be used in connection with the operations of the fleet and for submarine hunting and general aerial coast patrol work.

The Unit No. 1 participated in the "Mosquito Fleet" manœuvres during the week of September 5th to 12th last, under most adverse weather conditions. On September 9th one of the Curtiss seaplanes of the Unit went out to look for the two torpedo boat destroyers representing the enemy attacking fleet, and when they were about twenty-five miles outside of New York Harbor, they were caught in a thunder storm, but they located the torpedo boats, unknown to the latter and reported them to headquarters. The feat was most remarkable and convincing, and revised the opinion of naval men regarding the possibility of employing civilian aviators in naval operations. The work of the unit was so convincing

(*Continued on page 77*)

THE NEWS OF THE WEEK

First U. S. Dirigibles Ready in a Month

Washington, D. C.—Builders of the sixteen small non-rigid dirigible airships recently ordered for navy coast patrol work in co-operation with aeroplanes expect to deliver the first ship for trial flights within a month. The builders are co-operating closely in their efforts to produce the airships in the shortest possible time.

Representatives of aircraft and rubber companies were again in conference at the Navy Department with the joint army-navy board laying plans for construction of large, rigid battle craft similar to Zeppelins. The navy believes such airships would be valuable scouts.

Mr. Dodge's Aeroplane Camp

Newport, R. I.—Mr. William Earl Dodge will establish his aeroplane camp on the beach at the southern end of Newport Harbor, this Spring.

New Packard Aircraft Engine Nearly Ready

The 200 horsepower aircraft motor of the Packard Company is about ready to take flight. The process of installing the engine in specially constructed planes is now going on rapidly, and the first ascension probably will be witnessed within a fortnight.

Final work on the motor has been hastened by developments in the international situation that may create an urgent need for aircraft in America.

The flying tests of the new engine will be made at the Joy aviation field, near Mount Clemens, Mich., where there are unusual facilities for trials over both land and water.

W. B. Stout, chief engineer of the Packard aircraft division, says that the machine will not be capable of more than ninety miles an hour, because of the peculiar construction of the planes made for it, but it will be capable of mounting quickly to great heights. His observation is that the machine promises ability to ascend with at least six persons.

The tests probably will be conducted by Frank Coffin.

For Aerial Sharpshooters

Detroit, Mich.—Information was received here from Los Angeles that De Lloyd Thompson, a well-known aviator, telegraphed to eleven famous American automobile drivers inviting them to become members of an aviation unit to serve the Government in case of war. The proposed unit would be known as the Aerial sharpshooters.

The racers whom Thompson has invited are Barney Oldfield, Dario Resta, Ralph De Palma, Eddie Rickenbacher, Johnny Aitken, Howard Wilcox, Earl Cooper, Eddie Pullen, Wilbur d'Alene, Thomas Milton and Eddie O'Donnell. All of these men, it is understood, have made flights with Thompson.

Thompson plans to have the units train in Detroit, where suitable quarters are available. Rickenbacher is one of the leaders of the movement.

Princeton Aviation Corps

Princeton, N. J.—For the proposed aeroplane corps at Princeton University, more than 200 men have signed, and the committee of undergraduates is now practically assured of having machines here within a short time. The corps will be entirely independent of Government supervision and the alumni who are backing the plan will defray the expense of machines and mechanics and pilots. For the first squad of thirty men who will be selected to receive training with the machines a rigid competitive physical examination will be held shortly. A camp will be established at Princeton, where the students will be instructed daily until they can handle efficiently their machines, after which a new squad will be chosen. No selection has been made so far of an instructor, but an officer of the club declared today that a man with experience in France would most likely be chosen.

To Teach American Pilots

New York City, March 19—Lieut. Edward A. Kelly, an American aviator, who for the last year and a half has been with the British Flying Corps, arrived yesterday on the Lapland to assist in instructing American fliers at Mineola. He brought with him the plans and a model of the Vickers aeroplane, the fastest machine in existence, according to Lieut. Kelly.

Its tremendous speed, claimed to be almost 160 miles an hour, together with its easy control, make it ideal for scouting purposes, he said. The engine is made from a new alloy which is much lighter than iron or steel.

Lieut. Kelly has been wounded three times, the last time in the right leg by shrapnel while he was bringing down two German machines at the Somme. He descended inside the British lines and was taken unconscious from his machine. He is still lame and is on indefinite furlough.

Northwestern Aeroplane Co. Incorporated

Minneapolis, Minn.—The incorporation has been announced of the Northwestern Aeroplane Company with an authorized capital stock of $200,000, for the purpose of manufacturing aeroplanes and conducting a flying school.

A flying field has been contracted for, and the company will start building military scouts of thirty feet wing spread. Charles M. Peters, a former pupil of Lincoln Beachy, and an exhibition flier of five years' experience, will be general manager. The other officers are: G. Reid, president; L. E. Barrett, vice-president; Jesse Van Valkenburg, secretary and treasurer, and H. M. Westholz, superintendent of construction.

Richardson Aeroplane Co. Active

New Orleans.—Frank T. Richardson, president of the Richardson Aeroplane Corporation, Inc., with offices in the Whitney-Central building here, is in New Orleans from Washington and announces that work on the erection of the aeroplane plant in New Orleans, on the banks of the Orleans canal, near Lake Pontchartrain, will begin immediately.

Mr. Richardson made several successful tests of his new biplane at the Washington naval testings grounds.

The principal feature claimed for the machine is its inherent longitudinal stability and the tandem effect, making it impossible for the machine to take over a ten-degree angle in any direction. A demonstration flight from New Orleans and return will be made.

Mineola Notes

The twin-motored Curtiss tractor which was shown at the Aeronautic Exposition last month, is now assembled at the Aviation Station at Mineola. It is equipped with complete Sperry gyroscopic stabilizing apparatus, and a gun mounted at the nose of the machine makes it particularly adaptable for defense purposes.

The most recent addition to the field is the new Standard "J" which was shipped there last week from Daytona, Florida. Overton Bounds, accompanied by his mechanician Nick Shreyer, has returned from the south after a stay of three months, in which time the "J" was put through its high and low speed tests. The "H3" was also satisfactorily put through all the tests required of it by the War Department. Further tests will now be made at Mineola.

There are now more than twenty-five aeroplanes at Mineola, including three Standards, four L. W. F.'s, the twin-motored Curtiss, and the rest Curtiss J. N.'s.

Remy Re-Elects Directors and Officers

Detroit, Mich.—At a meeting of the stockholders of the Remy Electric Co., all directors and officers were re-elected.

Army aeroplanes landing in the snow at Mineola, Long Island, in the recent aerial maneuvres.

The latest Standard military tractor, equipped with Hall-Scott motor, at Mineola.

Curtiss School News

Miami, Fla.—The first solo flights at the Curtiss aviation school of Miami Beach were made last week by E. H. Holterman, of Woodstock, Vt., who acquitted himself creditably and won the praise of his fellow students and the instructors.

Mr. Holterman has been a close student under the able instruction of Captain Roger Jannus.

Not only has Mr. Holterman qualified in his efforts to become an aviator, but has passed the test and qualified for the United States Government and the Aero Club of America.

"Solo" flights are made without assistance of the instructor, and include landing within four feet of a designated mark; five "figure eights" between marks sixteen hundred feet apart, concluding with a landing within one hundred and fifty feet of the mark.

Another test requires the student to make five "figure eights" at an altitude of one thousand feet or over, and at this height to shut off the motor and glide down, making right and left banks at an angle of ninety degrees and landing within one hundred and fifty feet of the mark.

Favors Bill to Prohibit Hazardous Air Feats

Boston, Mass.—Godfrey L. Cabot, president of the Aero Club of New England, has requested a legislative committee to report favorably a bill to prohibit "looping the loop," vertical diving and other hazardous feats by aviators. He said there were only 100 competent aviators in the country, all of whom would be needed for Government service in case of war. The measure, he pointed out, was framed to conserve the lives of these men and those about to enter the service. There was no opposition.

Col. Lewis Sends Royalties Check to War Department

It is learned that Col. Isaac N. Lewis, U.S.A., inventor of the automatic rifle which bears his name, has sent to the Secretary of War a certified check for more than $10,000 covering the amount of royalties Colonel Lewis has received from the manufacture of his machine gun for the United States Government—and those in use by this Government even if not manufactured in the first instance for it. In his letter to Mr. Baker, Colonel Lewis said that he had absolutely not the least doubt that he was legally entitled to retain these royalties, but having maintained the position that the gun had been offered free to the United States, he preferred to conform to this attitude to the minutest detail. Colonel Lewis did not believe that the fact that he is a retired officer of the Army, entailed upon him any restraint from accepting and using such financial recompense as might come through his invention. The Secretary of War submitted the matter to the Judge Advocate General of the Army for an opinion as to whether the check could be accepted by the Department. Just what was the view of General Crowder could not be learned, but the papers, bearing his endorsement, were then sent to the Secretary of the Treasury for final action. This action of Colonel Lewis is significant in view of the statements intended to discredit his assertion that he had offered his gun to the Government free from all royalties to himself.

Army Maneuvers at Mineola

Mineola, L. I., March 22.—Twenty-five aeroplanes, piloted, some by regular army officers and some by civilians under training, composing, according to army officers at the aviation station here, the largest group of fliers that have ever taken the air together at any place in this country, went up from the Government field to make observations over a theoretical enemy somewhere in the vicinity of Mineola.

An enemy regiment—so dispatches had reported—was encamped in the vicinity. The problem was to find their trenches, such of their forces as were on the march, their motor transports, and their artillery. The fliers took the air at 3 o'clock, and within an hour and twenty-five minutes all of the information was in the hands of the officers at headquarters on the aviation field. Most of the aeroplanes had returned within forty minutes, but the squad assigned to locating the motor truck did not accomplish its mission until the truck was within three miles of the field.

The army officers and the flying instructors were much pleased with the test, which was made without any mishaps and according to schedule. The twenty-five machines took the air in squads, to each one of which had been assigned a special mission. They ascended to heights varying from 6,000 to 8,000 feet, except the squad which had been ordered to detect the artillery fire of the enemy, which flew at about 2,000 feet.

A trench 100 feet long had been dug about three miles from the camp. Near it was an imaginary regiment represented by strips of white cloth. The motor truck which started from Far Rockaway represented a supply train, and was covered with black and white stripes. Smoke bombs were sent up to represent the artillery fire.

In each machine were an observer and a pilot. They took with them maps of the country, sketching pads, and cameras. Captain J. W. Butts of the First Signal Corps operated a camera by a revolving propeller, which permitted the taking of several hundred photographs within a short period.

The artillery fire was located first, and soon afterward a second squad returned with news of the position of the imaginary regiment. The trench also was found within a comparatively short period. The motor in the meantime had been continuing its run to Mineola, meeting on the Long Island Parkway a number of other machines, from which at a great height it was hard to distinguish it. It had arrived at Hempstead Village before the aviators discovered it.

The officers who made the flight were Captain R. C. Bolling, Lieutenant J. E. Miller, Captain J. E. Butts, Lieutenant L. T. Wheaton, Lieutenant S. H. Wehrle, Corporal W. P. Willetts, Sergeant E. R. Noyes, and Lieutenant H. H. Reynolds.

Aeroplane Consolidation Project Broken Off

According to a despatch in the Wall Street Journal negotiations which have been under way for several weeks for consolidation of the Wright-Martin Aircraft Corp. and the Curtiss Aeroplane & Motor Corp. "have been broken off and it is unlikely that they will be resumed."

"Tex" Millman is Buried

With military honors of the air,—the first time that such honors have been paid in America, "Tex" Millman, twenty-two years old, aviation instructor at the U. S. Aviation School at Mineola, was buried March 21st.

"Tex" was a good pilot. Although he had never won fame for any death-defying feats of the air, he was known as being as steady and intelligent a pilot as this country possesses. He was one of the youngest men in the game of young men, and was master of practically every make of aeroplane. He did not hesitate, but was always ready to take up any aeroplane, so long as it was capable of flying. Yet with all this varied experience on different types of machines "Tex" never had an accident,—**never broke a stick.** And it was not an airman's death that Peter Carl Millman died, for it was pneumonia that took him off, shortly after the great aeroplane manoeuvres at Mineola, when a fleet of 16 machines took part in a sham battle.

Immediately after the church ceremony eleven aviators went to the aviation field to prepare for the military honors, as the funeral procession made its way to the cemetery. In a little while the roar of the machines could be heard.

Into the air soared machine No. 167, driven by A. L. Allan. Then followed ten more aircraft, piloted by F. A. Bjorkland, H. H. Salmon, Lieutenant C. H. Reynolds, Sergeant L. C. Smith, Lieutenant Ivan P. Wheaton, Corporal B. L. Watkins, W. H. Blakley, W. C. Jenkins, H. H. Simons and W. L. Willetts.

Rising to an altitude of from 800 to 1,000 feet, Allan led the flyers in ever-widening circles, until a 'plane was passing every few minutes above the tiny spire on the chapel of St. Brigid's. Three times the aviators circled. And when at last they were describing a great ring the radius of which was some three miles the circles began to narrow.

While eight aviators were guiding their craft above the cemetery proper, three 'planes began a spiral descent. Suddenly the hissing sound a biplane makes when it is volplaning downward with its motor cut off was heard.

A great warbird whizzed low over the Post Road, rose suddenly again to escape the telephone wires strung on the west side of the graveyard, and skimmed onward. A second later the craft was over the grave, while from the hand of Aviator Allan there fell a bunch of carnations. The flowers landed perhaps a yard past the fresh earth.

A few moments passed, and Bjorkland sped to within fifty feet of earth. The flowers he flung landed almost in the grave, just at the feet of the pall-bearers.

As Bjorkland threw on the power and rose "June" Salmon flew low and dropped two wreaths. Then he, too, sped upward and onward to rejoin his circling comrades.

Greater and greater once more grew the flying ring. Three times more, as if in final salute, the aviators circled. Then, one by one, they passed over Garden City, and volplaned swiftly past the high board fence and the group of hangars for a landing on Mineola field.

Aeroplane Company for Montana

Great Falls, Mont.—Articles of incorporation have been filed with the Secretary of State providing for a stock company of $500,000 at Great Falls which expects to enter into the business of manufacturing aeroplanes for use in the Army, Navy and for private citizens.

It is known as the Russell Aeroplane Company and its directors are E. S. Russell, E. L. Shields, George Russell, Frank Hodous and George A. Minson, all of Great Falls.

Army and Navy News

Major William Mitchell, Signal Corps, U.S.A., who is one of the four aviation officers selected to go to France, left Washington March 17 for Havana, where he will embark for some French port. Major Mitchell will concern himself principally with the organization of the French air squadrons behind the line and the methods used in keeping them in trim for active service.

Efforts will be made as soon as the 65th Congress gets down to actual business to have included in the Army legislation some authorization for the War Department to train unenlisted volunteer aviators. This was urged in the closing days of the last session by Representative Mann, but no action was permitted. Representative Crago, of Pennsylvania, it will be recalled, proposed an amendment appropriating $1,000,000 for aviation purposes in the National Guard, but Mr. McKellar, from the same state, vigorously opposed the motion and it was killed on a point of order.

The Naval Militia aeronautical station of the 1st Battalion, N.M.N.Y., which was operated at Bay Shore, L. I., last summer will be continued this year with increased equipment. Plans have been drawn and bids requested for the erection at Bay Shore of hangars, living quarters and mess hall. The Navy Department probably will loan to the Naval Militia a large tractor seaplane for use in instructing recruits in scouting flights over the sea, and it is unofficially reported that a fund is being raised to purchase another seaplane capable of making ninety miles an hour, with a cruising radius of 400 miles. These machines, with the flying boat already on hand, will make the 1st Battalion of New York one of the best equipped volunteer aeronautic units in the country. It is expected that at least twenty well trained aviators will be turned out during the summer.

Col. William G. Haan, C.A.C., is designated as aeronautical officer of the Eastern Department. (March 16, War. D.)

Mess. Sergt. Irwin N. Zuber, C.A.C., 2d Co., Fort Du Pont, Del., is transferred as private to the Signal Corps and will be sent to Fort Omaha, Neb., for duty at the U. S. Army Balloon School. His appointment as sergeant, Signal Corps, is announced. (March 16, War D.)

First Lieut. Bee R. Osborne, Aviation Section, S. O. R. C., to active duty at Fort Sam Houston, Texas, 3d Aero Squadron, Signal Corps. (March 15, War D.)

Leave one month to 1st Lieut. David R. Wheeler, Aviation Section, S.O.R.C. (March 14, War D.)

Par. 49, S.O. 59, March 14, 1917, War D., relating to 1st Lieut. David R. Wheeler, Aviation Section, S.O.R.C., is amended so as to grant leave for ten days instead of one month. (March 16, War D.)

The following promotions, appointments and reductions in the Aviation Section of the Signal Corps, U. S. Army, are announced: To be sergeants first class: Pvts. Charley Miller, Feb. 22, 1917, and Roland G. Blake, March 5, 1917. To be sergeants: Corpls. Howard M. Logan, Samuel Salansky, Charles A. Moody, Israel Cote, Oliver Hall, Fred Mittenberg, Remorse Lovell, Roy H. Teernstra, Castor Nielsen, Frank Conger, Paul B. Begovatz, Fred P. Schoberle, Fred E. Waitt, Christian M. Sorenson and Benjamin F. Stahler, and Cook John J. Harrison to date March 16, 1917, and Pvt. Kazimierz Wajdowicz, Feb. 22, 1917. (March 16, C.S.O.)

Sergt. George I. Sullivan, S.E.R.C., Fort Monroe, Va., to active duty in the Aviation Section, S. E. R. C., with station at the Curtiss Aviation School, Newport News, Va., March 20. (March 17, War D.)

Sergt. Daniel Buckley, S.E.R.C., Fort Monroe, Va., is assigned to active duty in the Aviation Section, S.E.R.C., with station at the Curtiss Aviation School, Newport News, Va. (March 15, War D.)

Sergt. Thomas M. Ring, S.E.R.C., Fort Monroe, Va., assigned to active duty in the Aviation Section, S.E.R.C., at the Curtiss Aviation School, Newport News, Va., March 20, 1917. (March 17, War D.)

Sergt. Raymond B. Quick, S. E. R. C., Fort Slocum, N. Y., to active duty in Aviation Section at the Curtiss Aviation School, Newport News, Va., March 25. (March 21, War. D.)

Capt. Clarence C. Culver, Cav., U.S.A., who has been for several months detailed to the Signal Corps Aviation School at San Diego, Ca., was ordered to Washington during the past week for duty in the office of the Chief Signal Officer. Captain Culver has been specializing in radio work in connection with aeroplanes and is now considered an expert in that particular line. It is probable that he will soon be transferred to the experimental station at Hampton, Va., to continue the same work there. Lieut. Neil G. Finch, Field Art., who has been detailed in office of the Administration Division, Signal Corps, at Washington, has been transferred to Fort Sam Houston. He left for his new post on March 20.

First Lt. Paul L. Ferron, 6th F. A., detailed in aviation, section Signal Corps, and rated junior military aviator.

Col. William G. Haan, C. A., and Capt. Sheler W. Fitzgerald, junior military aviators, Signal Corps, detailed as members joint army and navy board for selection of sites for joint aeronautical stations on Atlantic coast.

Hydraulically Forged Steel Cylinders

The Tioga Steel & Iron Company, Philadelphia, Pa., have made a specialty for the past year of hydraulically hollow forging steel aeroplane cylinder forgings and have supplied a large quantity of these forgings to various aeroplane builders to their entire satisfaction. By their method of making these, the steel is closely confined in dies under enormous pressure, which makes the metal very dense and uniform, thus greatly increasing the physical properties and at the same time produces a superior wearing metal for cylinder construction. Thus aeroplane motor builders are not only able to save a considerable amount of machine work as compared to machining these cylinders from a solid bar or billet, but are assured of a much better cylinder and the elimination of pipes.

They are able to make these cylinders of high or low carbon, or alloy steels, such as chrome nickle, etc. They further carry at all times a large stock of steels which enables them to make very prompt shipments. They also make a specialty of forging propeller hubs, flanges and shafts, on which they are in position to make prompt shipments.

Their shop is equipped with large and small steam hammers and large and small hydraulic forging presses which enables them to cover a very wide field, and they have built up a very large business in the aeroplane and automobile field by being able to take care of rush requirements.

They have made a specialty of hydraulic pressed die forgings for many years and are leaders in this particular class of work.

The Late F. W. Roebling

Trenton, N. J.—Ferdinand W. Roebling, treasurer and general manager of the John A. Roebling Sons Company, builders of the Brooklyn Bridge and other great structures, and widely known in the wire rope industry, died March 16 at 222 West State street, this city. He had been ill for a month. Mr. Roebling was born in Saxonburg, Pa., February 27, 1842 and was a son of John A. Roebling, the pioneer wire rope manufacturer in this country. He received his education in the Polytechnic College, Philadelphia. He specialized in chemistry.

John A. Roebling began the manufacture of wire rope at Saxonburg in 1840 and he transferred his plant to Trenton in 1848. The wire rope industry was new then, for though wires for haulage purposes had been made in Germany in 1820, stranded wire rope was not made until 1834, and Mr. Roebling, Sr., was the first to manufacture it here.

S. K. F. Appoints Distributors

For the purpose of more readily supplying the requirements of the automobile trade and extending service to automobile users throughout New England, arrangements have recently been completed whereby The Post and Lester Co., of Hartford, Conn., has been appointed distributors of S K F ball bearings.

With branch houses in Boston, Bridgeport, New Haven, New London, Providence, Springfield, Waterbury and Worcester, The Post and Lester Co. will be able to supply S K F radial and thrust bearings from stock.

National Aero Institute Formed

Chicago, Ill.—There has recently been formed in this city the National Aero Institute, the purpose of which is to teach the basic theory of flight. The institute was formed by Mr. John A. Tenney, Secretary of the Advertising Association of Chicago, and the advisory board will include: Mr. Jas. J. Stephens, Vice-President of the Aero Club of Illinois; Mr. Arthur Nealy, President of the Model Aero Club of Illinois; Walter L. Brock, winner of the London-Paris race, Ellis Cook, who will be in active charge of the instruction, and the well known motor manufacturer and designer, Mr. Glenn Muffly.

Mr. Muffly will supervise the writing of the course and the organizing of the faculty. This new organization will not advertise "Learn to fly by mail" or any other unwarranted statement, but on the other hand, will submit all its advertising copy to the National Vigilance Committee of the Associated Advertising Clubs of the World. The idea will be, not to emphasize the money to be made by aviators, but the commercial future in aviation. It looks like a step in the right direction.

Will Fly to Washington

Franklin, Pa.—Congressman-elect O. D. Bleakley, of Franklin, of the twenty-eighth district, announced that when the special session of Congress begins in April he will fly either from Franklin or Philadelphia to Washington to take his seat. If a suitable landing place can be arranged at Franklin he will fly to and from the capital during his term.

The Grinnell tractor biplane, used by the Grinnell Company for instruction purposes.

AIRCRAFT MANUFACTURERS, AERO CLUB AND NATIONAL ADVISORY COMMITTEE DISCUSS SPEEDING UP AIRCRAFT PRODUCTION

The aircraft manufacturers of the United States and a committee from the Aero Club had an all-day meeting with the Executive Committee of the National Advisory Committee for Aeronautics in the office of the Advisory Committee, rooms 515-518 Munsey Building. The meeting was presided over by Dr. Charles D. Walcott, chairman of the Executive Committee. The object of the meeting was to consider ways and means to speed up the nation's aerial preparedness. A special committee composed of Mr. Henry Woodhouse, Mr. Augustus Post and Congressman Hurlburt represented the Aero Club of America.

The principal development of the meeting was the appointment of a special committee of seven to arrange details for speeding up production of aircraft and temporary standardization of types of aircraft to be required by the Army and Navy. This committee will consist of four members of the National Advisory Committee for Aeronautics and three representatives of the Aircraft Manufacturers' Association.

The prospective needs of the Army and Navy for the next two or three years were discussed. The apportionment of orders by types to the factories with the best facilities for quantity production, and the standardization of materials used in aircraft were considered. There was discussion of the steps that should be taken by the Government to mobilize the important materials that will be necessary in aircraft manufacture, and of the policy of the Army and Navy in the testing and inspecting of engines, materials, and completed aircraft.

There appeared to be strong sentiment in favor of a cross-licensing agreement of aeronautic patents. Mr. Coffin and Mr. Waldon explained the steps in the organization of the National Automobile Chamber of Commerce, and the applicability of similar measures to the aeronautic industry.

The following is a list of those present at the meeting: Dr. Charles D. Walcott, Chairman; Dr. S. W. Stratton, Secretary; Dr. Joseph S. Ames, Dr. Charles F. Marvin, Dr. Michael I. Pupin, Brig.-Gen. George O. Squier, U. S. A.; Rear Admiral D. W. Taylor, U. S. N.; Lieut. J. H. Towers, U. S. N.; Mr. Howard E Coffin, Sidney D Waldon, Henry Woodhouse, Aero Club of America; Augustus Post, Dr. W. Christmas, Christmas Aeroplane Company; Mr. G. R. Cockley, nternational Airship Corporation, Gary, Indiana; Mr. A. H. Flint, L. W. F. Engineering Company; Mr. Henry M. Frauenthal, Secretary, New York Aero Construction Company; Mr. E. F. Gallaudet, President, Gallaudet Aircraft Corporation; Mr. B. A. Guy, Curtiss Aeroplane Company, Buffalo, N. Y.; Mr. G. H. Houston, General Manager, Curtiss Aeroplane Co.; Mr. William H. Hutton, Aviation Section, War Department; Mr. C. M. Keyes, The Curtiss Aeroplane Company; Mr. Glenn L. Martin, Wright-Martin Aircraft Corporation; Mr. H. B. Mingle, President, Standard Aero Corporation; Mr. W. B. Judkins, Vice President, Standard Aero Corporation; Mr. F. L. Morse, Thomas-Morse Aircraft Corporation; Mr. Israel Ludlow, Mr. C. T. Moore, Scattle, Washington; Mr. F. H. Russell, Burgess Co.; Mr. J. W. Scott, Vice-President, Curtiss Aeroplane Co.; Mr. Henry Harrison Suples, National Venier Products Co., New York City; Mr. G. Thomas, Sturtevant Aeroplane Company; Mr. Inglis M. Uppercue, Aeromarine Plane & Motor Company; Major C. S. Wallace, U. S. A. Signal Corps, War Department; Mr. Lee S. Wallace, United Eastern Aeroplane Company; Mr. Harry D. Westcott, New York Aero Construction Co.; Benj. L. Williams, Secretary, Aircraft Manufacturers' Association; Mr. Charles F. Willard, Aeromarine Plane & Motor Company; Mr. Samuel Quinn, President, International Airship Corporation; Mr. Eugene S. Robinson, United Eastern Aeroplane Corporation; Mr. Charles B. King, Signal Corps, War Department; Mr. F. S. Dusenberg, President, Dusenberg Motor Corporation; Warren S. Eaton, New York Aero Construction Company.

The opening address of Dr. Charles D. Walcott, Chairman, was as follows:

Object of Call—To-day's joint meeting of the National Advisory Committee on Aeronautics, the Aircraft Manufacturers' Association, and representatives of the Army and Navy is called for the purpose of considering ways and means by which to speed up our Aerial Preparedness.

Congress has generously responded this year with large appropriations with which to establish air fleets for both the Army and Navy and yet a careful review of results accomplished thus far clearly indicates that, with the passing of the first year of our active aerial program, we shall appear to have hardly made a beginning.

Aeronautic Industry—The aeronautic industry's inability to meet the needs of the Government is in itself only another example of the fact that though millions may be available for a specific purpose in time of great need, no amount of money will buy time. Even the most generous appropriations do not open up the years that have passed and enable us to carefully lay the foundations of a great industry and a great aerial arm through the education of engineers, manufacturers, teachers and all of the wide variety of personnel required. An aeronautical engineer, for instance, does not step full fledged into begging, but is the result of years of patient study of and experience with aircraft. Such an evolution can only be accomplished with time.

Government Support—The aeronautic industry requires government support in its development, and this it has not received in the past in this country in a measure sufficient to enable it to meet the present enormous demands that have suddenly been made upon it. During the eight years prior to 1916, the Army ordered 59 aeroplanes and received 54. These were all supplied by four makers, and the largest number ordered from any one maker was 32 machines, not a very large amount of encouragement over a period of eight years.

During 1916, the Army ordered 366 planes and received 64. These planes were divided up among nine factories, which factories represent practically the entire producing capacity of the country. Whatever the industry may produce during 1917 is bound to fall far short of the country's needs and our meeting to-day is for the purpose of ascertaining how the situation might be helped.

Aeronautics in Europe—The tremendous urge of a life and death struggle in Europe in which command of the air is all important, has stimulated the aeronautical industry over there into a tremendous development. New models succeed new models in rapid succession in the feverish race for air supremacy and only the most perfect and up to the minute aircraft are permitted to reach the fighting lines.

The potential fighting strength of this country, if properly trained and equipped, is greater than that of any of the European countries with the possible exception of Russia. We are enormously wealthy as a nation with a tremendous coast line to protect. Whatever else in the line of preparedness we may excuse delay in we must not permit anything to stand in the way of the upbuilding of our aerial defense. It is not impossible to believe that a good navy supplemented by an adequate aerial organization, and equipment, to maintain command of the air would go a long ways in an emergency toward making up for an inadequate or imperfectly trained fighting forceon land.

We want all types of planes in large quantities, for training, reconnaissance, bomb dropping, fighting, etc., for both army and navy use. We want them as good, or better than, the best European types. We want the skilled aviators in equally large quantities to handle these various fighting machines and we want the whole program completed at the earliest date.

Present Facillties—At the present time there are not more than twelve aeroplane manufacturing organizations in the U. S., with the necessary engineering and manufacturing experience and facilities to justify government business. The first conclusion to be arrived at is, therefore, that these factories must be encouraged to expand as rapidly as possible to reach a capacity of planes pe ryear that might be considered as our reasonable needs.

Estimates of Needs of Aircraft—There are many estimates of our reasonable needs, and the one herewith presented has been prepared after conferences with as many men as could be reached who have experience or judgment qualifying them to express an opinion, and after obtaining as much data as possible from Europe.

Tentative estimate of annual requirements of aeroplanes (assumed to be possible of accomplishment in 1919):

	Planes	Aviators
Attached to an army of 1,000,000 men (that is, 1 plane per 1,000 men	1,000	1,000
Attached to our fleets at sea	300	200
For harbor and seaport defense	600	800
	2,000	2,000
For training pilots (worn out or broken)	2,000	400
	4,000	2,400

The last item of training machines is arrived at as follows: It has been found best to divide the students into assignments of five per instructor. European experience shows that it takes at least nine months to produce a properly trained advanced military aviator and that it costs approximately one and a half machines in wear and tear and breakage for each finished aviator. The breakages are most often made by the men who fail to qualify. Assuming that it would be desirable for many reasons to limit each military aviator's active duty, exclusive of war time, to one year, then we must each year produce 2,000 new aviators. Disregarding failures 400 instructors should turn out five finished advanced military aviators, each with a minimum of nine months' instruction. It is probable that the longer the time allowed and the more careful the instruction the lower would be the percentage of planes used up per aviator. Instead of 1½ per aviator we have figured only 1, or at the rate of 2,000 planes per year to produce the 2,000 finished fighting pilots.

If we assume that the above figures are approximately correct, then an industry that delivered to the Army and Navy less than 100 machines during the eight years prior to 1916, less than 100 machines during 1916, and which will deliver somewhere around 600 planes during 1917, has still to be very greatly expanded in order to reach what may be considered the reasonable requirements of the country.

Cooperation of Army and Navy—To facilitate this necessary increase of output, without the opportunity at the moment of increasing the number of different sources of supply, demands the closest cooperation between the Army and Navy and the industry in order to eliimnate very stroke of unnecessary effort and in order to concentrate all our activities upon the fewest number of types and designs of each that will completely meet our needs.

Efficiency in Manufacture—It is entirely unnecessary, for instance, to have five companies all producing a different design of training machine to do the same work. One of the five is best and when determined should be made the standard until a better is developed.

Again, with so few sources of supply, it is imperative in the interest of efficiency to not have every manufacturer producing every type, but, for instance, to allot all of the types where they can be best produced. In this way each factory will concentrate on the one or two types that it knows most about and will have volume enough to make for more economical operation and better prices. This should greatly stimulate improvement of types, for not only would a large amount of duplicate designing be avoided, but each engineering staff would be concentrating all its efforts on some particular part of the government program that had been assigned to it.

It is highly desirable at this time that there should be a very active campaign carried on in the standardization of the more common parts and fittings of planes and motors, so that when we may have arrived at such an output at 4,000 planes per year there shall be the greatest degree of interchangeability of those parts and fittings in the interest of prompt field repairs. It is also important that all of the materials themselves should have standard specifications acceptable to both Army and Navy alike.

Inspection—Must, can and should be accomplished in reconciling the many differences that exist between the inspection systems of the Army and Navy as affecting aircraft. There is room for some simplification, for the removal of some duplication of effort between the departments and between them and the manufacturers and for a standardization of practice. Considering the rapid increase in output that must be made during the next two years, it is important that this problem be intelligently handled now.

Speeding Up of Production—In order to successfully speed up production, plans will have to be laid at once and steps taken, preferably by the government, to provide in advance of actual need the different kinds of material that are had to obtain, but which must be available in large quantities. For instance, if the industry is to plan on producing 2,500 planes during 1918 and 4,000 during 1919, then there should be about 2,500,000 feet of spruce air drying right now for next year, and we should be laying down 4,000,000 feet to take care of the year after. There are about five or six items of this kind that it is decidedly to the government's interest to handle promptly in order to insure

(*Continued on next page*)

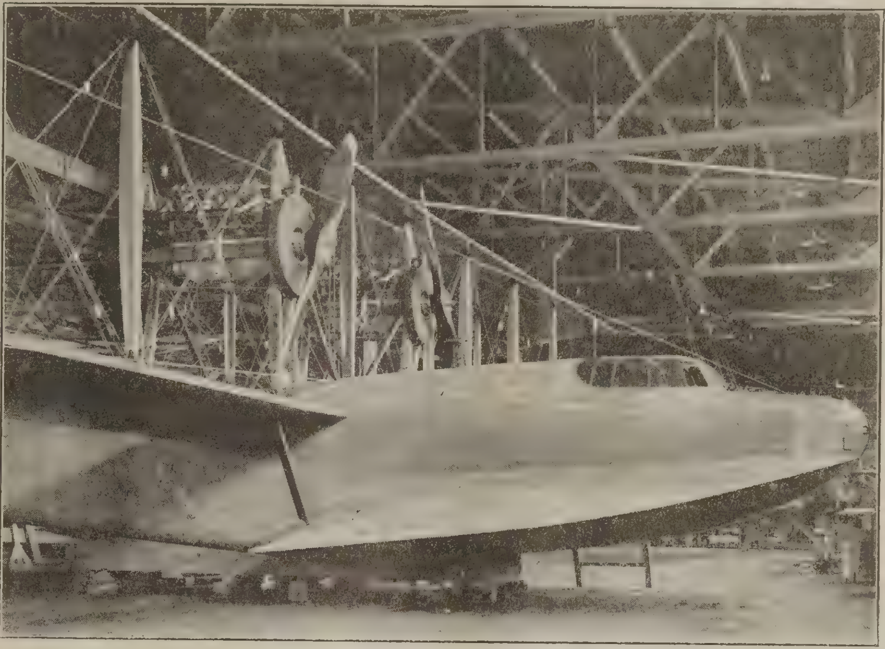
CURTISS MODEL H-12 FLYING BOAT

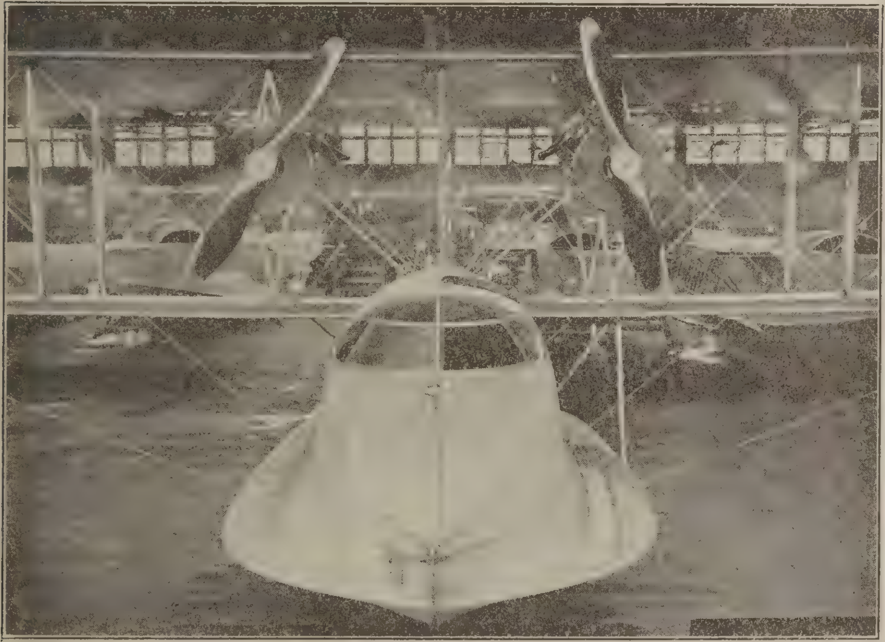
The Model H-12 flying boat, built by the Curtiss Co. for the U. S. Navy, is the largest type of flying boat in the world. First trials are to be given it at Pensacola, Fla. Although the H-12s have been turned out in large numbers for use in European navies, the demonstration flights at Pensacola will be the first to have been made by such a machine in this country.

In spite of the gigantic proportions of the boat it is easily controlled by one pilot. Four or five passengers besides the pilot can comfortably move about in the cockpit. The cockpit is entirely covered over by a hatch provided with celluloid windows permitting vision in all directions. This not only protects the occupants from the wind when in flight and spray when alighting, but also carries out the smooth effect of the hull to decrease wind resistance and skin friction.

List of general dimensions, areas and weights:

Wing span, upper plane	92 ft. 8½ in.
Wing span, lower plane	66 ft. 11½ in.
Total supporting surface	1120.78 sq. ft.
Gap between wings	8 ft. 0 in.
Height over all	16 ft. 9¼ in.
Net weight of machine, empty	5,945 lbs.
Useful load (as listed below)	2,044 lbs.
Motors (2) each 200 h.p.	400 h.p.





Useful load is figured as being composed of pilot and passenger each weighing 170 pounds; oil, 148 pounds, and gasoline, 1,556 pounds. In shorter flights the quantity of oil and fuel can be decreased and passengers carried of equal weight.

Twin motors of the Curtiss Model V2 are supported between the planes with the propellers in tractor position. Forward of the motor-carrying struts the circular radiators are located, through which the propeller shafts project. The V2 motor is an eight-cylinder V type, four-stroke cycle, rated at 200 h.p. at 1,400 r.p.m. Bore, 5 inches; stroke, 7 inches. Ignition is by two high-tension eight-cylinder magnetos and cooling by water circulated by a centrifugal pump. Two Zenith carbureters.

Gasoline consumption per b.h.p. hour, .54 pounds; oil, .03 pounds. Weight of each motor with propeller hub, but without oil or water, 690 pounds. Dead weight per rated h.p., 3.45 pounds.

The boat is expected to attain a speed of eighty-five miles an hour, and leaves the water at approximately fifty-five miles an hour.

---

an adequate supply at the right time and at the right price.

Patent Situation—From the standpoint of our national defense it is imperative that patent matters be not allowed to impede this very vital industrial growth. Congress recently appropriated $1,000,000 for the purpose of acquiring by purchase, condemnation, donation or otherwise any basic patent or patents that may be necessary to the development of the industry. It is not the desire of the National Advisory Committee on aeronautics in whose hands the matters rests at the moment for recommendation to condemn or purchase any patent. It believes that such action would be construed as indicating an unreasonable attitude of mind on the part of the owners of the patents condemned or purchased, besides perhaps serving to discourage invention, if the settlement was made on too low a basis or to encourage all sorts of claims upon the industry and the government, if such settlement was on too high a basis. The Committee is therefore working diligently upon the proposition of arranging an adjustment out of courts whereby just recognition will be made to the owners of the more important or basic patents in the form of reasonable royalties to be paid by the purchasers of planes, whether for military or civil use.

Tests of Finished Aircraft and Payments—Some difficulty has been experienced at times through inability to secure tests of finished planes. The present requirements that every machine produced be tested against its specifications sometimes works a hardship on the manufacturer, who must keep his product moving and his capital turning over, when a long spell of bad weather precludes test flying. This situation will probably grow much worse instead of better as the result of a rapid expansion of the industry, and calls for careful consideration and some revision of the present arrangements in order to still arrive at the same result, but without any inconvenience or handicap to the industry. The government must of necessity surround the disbursement of the public funds with ample safeguards, but the government cannot afford to impose any unnecessary burdens upon the rapidly growing aircraft industry, and it is hoped that some helpful suggestions may be offered at this meeting looking toward improvement along this line.

Aviation—One of the really serious problems is the matter of obtaining enough competent instructor aviators to teach the very large number of young men who are applying for commissions in the Officers Reserve Corps, Aviation Section. It is apparently going to be just as serious a matter to build up an adequate force of teachers of the advanced science of military flying as now practiced abroad as it is going to be to produce the machines that are to be flown. The Army and Navy Departments are endeavoring to secure from Europe the release of the Americans serving on the western front to form the nucleus of such an advanced training organization. Both departments, however, will require the fullest cooperation of the industry and of all private schools in bringing all those who are especially gifted into this line of work.

THE GERMAN AEROPLANE ENGINE TRIALS

A Detailed Description of the Equipment and Proceedings*

When the special rocking cradle system (described in Aerial Age for March 19) came to be tested fully, it was found that it possessed certain defects, which, however, were capable of being remedied.

Clearly this type of cradle responds to all re-actionary effects, some of which may not solely result from the torque of the crankshaft. For instance, it was discovered that the direction of the exhaust blast had an appreciable effect upon the readings, and steps had to be taken to exclude any interference from this cause. As the drawing (fig. 1) shows, in most cases the exhaust was discharged straight into the air through a short length of pipe practically tangential to the crankshaft. As the exhaust gases issued they created a small reaction at a large radius, the effect of which was by no means negligible, and this was overcome either by fitting a shield to the pipe to split up the exhaust stream into two symmetrical parts parallel to the crankshaft, and thereby eliminate the reaction, or by bending the pipe so that the discharge was radial to the crankshaft.

Another point to be considered was that the rotary air draught created by the propeller acted upon the cradle and set up a torque there in the opposite direction to the engine reaction. A shield could have been fitted to eliminate the rotary component of the air draught, but it happened that there was not time to make arrangements for this, and therefore, in the actual trials, the power of the engines was ascertained by running the engine under full load at certain speeds whilst driving a propeller, then disconnecting the propeller and fitting it to the specially calibrated electric motor, and so ascertaining what power was required to drive the same propeller in practically the same position at those speeds. It might be argued that the elaborate testing plant, with rocking cradle and so forth, might have been dispensed with and the power measured directly from the electric motor used in this way. The reply to this is that these electrical motors with rocking fields are expensive, require expert operators, and are only useful over a small range of power. The rocking cradle system is therefore recommended as being quite suitable for use by manufacturers, provided attention was given to the points above mentioned, and when this rocking cradle plant is once established it can be attended to by practically any tester, and, further, it can be used for engines of almost any size and type.

It might be of interest to state that torsional effect due to the exhaust gases entering the air practically tangential to the crankshaft might be anything up to 6%, and this, of course, must necessarily be added to, or subtracted from, the total reading, according to the side of the engine to which the exhaust pipes were fitted. On measuring the torsional effect upon the cradle due to the propeller draught when unshielded, it was found that this was about 8% to 10% of the total power absorbed by the propeller.

The decision of the judges to estimate the power absorbed by the propeller by driving it and running it at the same speed by the electric motor received some criticism from the competitors because it was objected that the power required by the electric motor to drive the propeller at a certain speed was less than that developed by the engine at the same speed. It was mentioned that the engine drove the propeller at a slight fluctuation of speed (propeller flutter) which called for higher power than was the case when the propeller was driven at a uniform speed as by an electric motor. This, however, is not a virtue of the petrol engine, and the engine had nothing to its credit on this account. Furthermore, the flywheel effect of the propeller is very considerable indeed. For instance, in the case of a 100 h.p. four-cylinder engine, the corresponding propeller gives a flywheel effect which permits a speed fluctuation of only .5%.

In practice the various indicating and recording devices previously described proved to be very successful, particularly the graduated flask used for short runs. This was particularly useful during the turning up of the carbureter by the competitor under varying atmospheric conditions, which was permitted during the preliminary test. The gradual loss of weight of petrol during the run was indicated at the observer's desk by an electric lamp which was switched on each time the beam passed the horizontal. It will be remembered that this occurred each time the weight of the fuel tank was reduced by 500 grammes. The oil consumption was also ascertained by weighing, and the weight pan of these scales hung down into the observer's room.

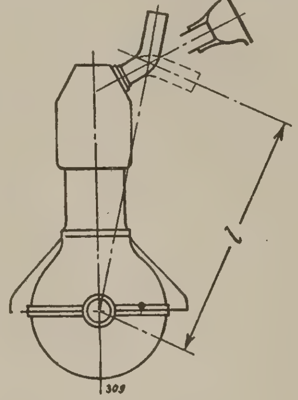


Fig. 1.

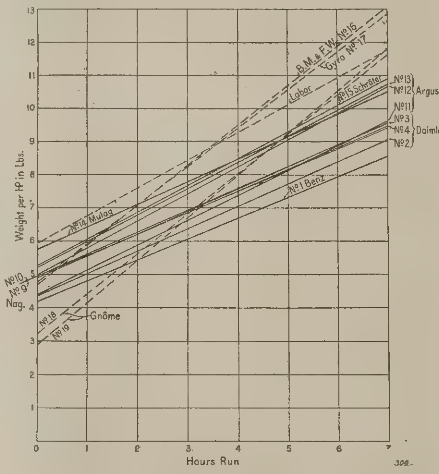

Fig. 2.

Curves showing weight per h.p. in relation to consumption.

The recording of the heat lost to the cooling water was not so easy, but great importance was attached to the accuracy of these records in order to arrive at the weight of the radiator required, as this had to be added to the weight of the engine and tanks inorder to find that of the complete power plant. One source of difficulty was the fact that the pipes were exposed to a big air draught from the propeller, and therefore all the readings were on the low side. It was one of the conditions of the trial that the weight of the radiator would be estimated at .128 lb. per 1,000 B.T.U., but this was found to be an incorrect estimate, and a better figure, which is made use of in the appended tables, is .390 lb. per 1,000 B.T.U. It is, of course, essential to stipulate some definite figure to arrive at the total weight of the plant.

The observer remained in the observer's room during the tests, entering up his records as they came along, while through a window he could see the engine being tested. In front of him was the electric bulb connected with the petrol consumption indicator. On the left was the scale pan from the oil tank and the taps for regulating the temperature of the cooling water, and the other recording and indicating devices were within easy reach. Furthermore, it was arranged that the operator actually running the engine should signal to the observer in the observer's room to inform him how the engine was running. For this purpose numerical signals were used. For instance, signal No. 1 meant that the engine was running well without vibration; No. 2, moderate vibration; No. 3, occasional misfiring, moderate vibration; No. 5, bad misfiring and bad vibration, and so forth. While, therefore, the observer was cut off from the noise of the engine, he could yet ascertain everything that was going on. The operator testing the engine had forms to fill in every hour, containing records as to petrol consumption and so on; these forms were checked with the recording instruments in the observer's room. By this means the tests were found to run off almost automatically with very small possibility of error.

The entries totalled sixty-eight, presented by twenty-six manufacturers, and list No. 1 shows the various engines entered and their performances. The tests made were as follows:

1. A preliminary test in which the engine was required to operate for fifteen minutes under full load, and for five minutes at its lowest speed. During this test the chief running conditions were recorded as well as the ease of starting.
2. Ascending test. The engine was started up in a horizontal position, and, whilst running under full load, was tilted 10° upwards, in which position it had to run for fifteen minutes under full load. The cradle was then suddenly tilted downwards, representing a sharp descent, and the engine had to run in this position first for five minutes under full load, and then for ten minutes throttled down as much as possible. Fnially, it had to be accelerated and run for five minutes under full load in the horizontal position again. In this test the acceleration of the engine was specially noted and marks allotted accordingly.
3. The main test, during which the engine had to run for seven hours without stop under full load. All that was permitted to be done was to control, from a distance of a yard and a half, the ignition and carbureter, oil, and fuel supply, and the test was broken off if the engine

* A radiator weight of 0.625 lb. per h.p. is assumed.

revolutions dropped to 85% of the normal for more than one minute. As a matter of fact, it was generally found that when this happened a serious fault developed, and the test in any case would have had to be abandoned. It was permitted to repeat the test (but only once) if the fault were a minor one such as a choked jet or stuck oil pump valves. Sooted sparking plugs rarely caused any trouble, and naturally most of the engines were fitted with dual ignition, so that little electrical trouble was experienced.

The chief actual engine troubles were sticking valves or valve rockers due to dust stirred up by the propeller, which naturally drew protests from the manufacturers on the score that the conditions under which the tests were run were not those under which the engine normally operated. It was, however, pointed out that frequently an aeroplane engine has to go through a dust cloud, as, for instance, when the machine is starting or landing on very dry ground.

One interesting cause of breakdown of a more serious nature was that of excessive cooling of the front cylinder due to the propeller draught. This set up unequal cooling, and in some cases caused the front cylinders and pistons to crack. This trouble can, of course, be overcome by fitting a shield to the front cylinder.

4. The final test. From the seventeen engines that passed the previous tests the ten lightest were subjected to a final test that consisted of two three-hour runs. During the first two hours the conditions were made very much more difficult. For instance, during one hour unequal cooling of the cylinders was produced by delivering a blast of air to one side of the engine. For half an hour the temperature of the water entering the jacket was increased from 90° C. to 95° C. Finally, during the last half-hour the engine revolutions were increased by 100 to 150. This was effected by mounting a separate propeller on the electric motor, in front of the one on the engine, and thereby creating a draught which lightened the load on the engine. These difficult tests had no detrimental effect on the ten engines.

Unfortunately, none of the air-cooled engines were able to take part in the final tests. Air-cooled engines of the rotary type only were entered, and, as these failed in the earlier tests, nothing in the nature of a comparison between air and water-cooling was obtained. Of the five rotary engines actually delivered, one was withdrawn, three did not develop their full powers, and also suffered from minor defects that apparently easily might have been avoided. The seven-cylinder 110x120 mm. Stahlberg engine, for instance, had to be withdrawn owing to severe carbureter freezing, as the tests were made during the cold and damp days of November. It was pointed out that in normal use the carbureter would be screened somewhat, and on this account the competitor received permission to fix up a screen and enter the competition again; however, he did not wish to do this, and the engine was withdrawn.

The seven-cylinder rotary engine of the Bayerischer Motoren Flugzeugwerke G.m.b.H. succeeded in completing the seven hours' test, but at a decreased output, because one of the high-tension wires dropped off, and it was decided that this engine could not compete in the final test owing to its high fuel consumption, which raised its plant and running weight to a prohibitive figure. This, of course, is one of the defects of the rotary engine, which rarely shines well in a competition of this kind, as, although the actual weight of the engine is extremely low, when consideration is taken of the weight of the fuel and oil required, together with the tanks for carrying it, say, for a seven hours' flight, the total plant weight is considerably in excess of that of a stationary engine.

This point becomes very clear in fig. 2, in which is shown the curves plotted for the plant weight of various engines on a run up to seven hours. The abscissæ represent time and the ordinates plant weight, and in arriving at this the size and weight of the tanks necessary to hold the required amount of fuel and oil have been calculated and added. The left-hand abscissa O refers to the weight per horse-power of the various engines *without fuel or oil tanks* (*i.e.*, for 0 hour run), and it will be seen that the rotary engines show on this line a very small weight per h.p. This, however, rapidly increases with the length of the test, the curves for the rotary engines quickly intersecting those for the stationary engines. This chart shows a curve for the 70 h.p. Gnome, although it was not entered for the competition; it is included as a matter of interest, the figures having been taken from the report by M. Lumet on the French trials. It will be seen that the plant weight of the actual prize winner, including radiator but *excluding* tanks, was half as heavy again as the 70 h.p. Gnome, but that at the end of a seven hours' run the weight per h.p. of the rotaries is about 37% to 38% higher than that of the prize winning stationary engine.

The accompanying Table I. gives the technical details of the competing engines, from which it will be seen that the six-cylinder engines proved to be slightly heavier than the four-cylinder ones. Thus the weight per h.p. of the four-cylinder Benz proved smaller than that of the six-cylinder Daimler, although the latter was provided with steel cylinders and other special features tending towards lightness. The winner also has the largest stroke-bore ratio, 180x130 mm., which produced a good-shaped combustion chamber, probably accounting for the low petrol consumption, viz., .53 pint per h.p. hour, equivalent to a thermal efficiency of about 29%. The oil consumption was not very low, and the mean effective pressure of 107 lb. per square inch was not particularly high. In the best Daimler engine this pressure was 114.2 lb. per square inch.

The engine speed was not limited by the conditions of the trial except that the propeller revolutions had not to exceed 1,350 to 1,450 r.p.m., according to output. The conditions, however, favored a very high speed engine with a reducing gear, in order to discourage the use of a small high-speed propeller which is inefficient. This, however, did not attract manufacturers, and only one engine with a reducing gear, the inverted Daimler, was actually entered, but this did not come anywhere near winning a prize, owing to its big weight and the fact that the engine speed was not sufficiently high to compensate for the extra weight incorporated in the gear reduction.

The results of some of the air-cooled rotary engines are also given (Table II.), and for the purpose of comparison there has been included the 50 h.p. Gnome engine, the figures for which were taken from those obtained in the previous French trials. Of chief interest is the loss due to churning of the air, and, according to M. Lumet, this amounts to 11% of the total h.p., which coincides well with the figures obtained in these tests. This has, of course, a serious effect on the output, as the mean effective pressure of about 75 lb. per square inch could at that time scarcely be increased. The fuel consumption is also bound to be high, so that these engines are badly handicapped as soon as flights of any serious duration are considered.

(*Continued from page* 70)

that the Executive Committeee of the Aero Club of America wrote a letter of appreciation to each of the members of the Unit, reading in part as follows:

"The Executive Committee of the Aero Club of America wishes to express its admiration for the splendid accomplishments of Volunteer Aerial Coast Patrol Unit No. 1 in connection with the aerial manœuvres held at Gravesend Bay on September 5th to 12th.

"Conditions obtaining at the time when one of your seaplanes located the two torpedo boat destroyers, the Flusser and the Warrington, make us realize that such a thing could have happened under war conditions and this achievement would have saved New York from being bombarded by the enemy's fleet.

"Owing to the fact that the United States Navy has only a few aeroplanes and trained aviators, in case of war the naval aviators available would barely be sufficient to operate at one of the naval centers or in connection with one of the squadrons of the fleet. We can conceive of the Flusser and Warrington representing a raiding squadron having succeeded in getting near New York, screened by the fog, and being found by one of the seaplanes of the Volunteer Aerial Coast Patrol Unit No. 1, thereby saving the ships at the entrance of New York Harbor from being destroyed and New York City from being bombarded. Your valuable work in locating mines also deserves commendation."

Following the manœuvres, the Unit went to New London, and carried out continuous experiments in cooperation with the naval authorities at the Naval Station. Upon their return to the University for their studies, the members of the Unit found Yale enthusiastic over their achievements, and they received hundreds of applications for admission in the Aerial Coast Patrol.

The twenty-nine men will train at West Palm Beach for six weeks, after which they will return to New York and train here. They will be joined by sixty others.

F. Trubee Davison and Robert A. Lovett are Chairmen of the Sub-committees on Enrollments and Training, and part of the Central Advisory Committee on Aeronautics, which is cooperating with Rear Admiral Nathaniel R. Usher in the organization of the Naval Reserve Flying Corps for the Third Naval District. Mr. Robert J. Ditman left for the U. S. Naval Aeronautic Station at Pensacola, Fla., two weeks ago to familiarize himself with the work they are doing there.

Mr. Lewis S. Thompson, a prominent New Yorker, a friend of the Davisons, has gone to West Palm Beach with the Unit to supervise the administration of the Unit.

The training, the cost of which will be paid for by Mr. H. P. Davison, will take place at the training camp at West Palm Beach, established by the American Trans-Oceanic Company, the organization established by Mr. Rodman Wanamaker to develop the plans for the Transatlantic flight. Mr. William D. Gash is President, Mr. Stewart McDonald is the manager, and David H. McCulloch is the chief instructor.

The Aero Club of America officials and officials of the Aerial Coast Patrol Commission, of which Admiral Robert E. Peary is chairman, commended the unit for their promptness in taking steps to prepare themselves to meet the national emergency.

THE TRAINING IN MILITARY AVIATION

(Lecture by General W. S. BRANCKER, R. A., Director of British Air Organization, before the Aeronautical Society of Great Britain)

(*Concluded from page* 19)

AEROPLANES AND ENGINES.

The next point which affects requirements of training is the provision of aeroplanes and engines. Here again controversy is eternally raging as to the best types to employ. Before the War, the general idea was that a beginner should be taught on the box kite, and this idea has lasted inasmuch that today nearly all our pupils start their instruction on a Maurice Farman. Personally, I have been opposed to this system, but I may be wrong and have given way to the majority, and I think from the instructor's point of view the Maurice Farman is a very nice, safe machine on which to get the pupil through his first experience of dual control in the air, althought in the actual movements necessary for controlling the machine it is different to almost any other machine in the Service. The 80 Gnome Avro has, beyond the Maurice Farman, been our stand-by in advanced training and is a thoroughly good machine for this purpose, light in handling, comparatively sensitive, and not too difficult to fly. For some time, pupils were successfully started on 80 Avros, but when Maurice Farmans are available in sufficient quantities the concensus of opinion has been that it was better to stick to that machine for preliminary training. Now, however, we have a new type, the first of which has just flown, which I hope will eventually eliminate the box kite type of training machine altogether. Another point on which much argument arises is the use of stable machines for training. When stable machines first came in, all the old conservative pilots shook their heads sadly and said that you could never make a good pilot on a stable machine; that idea has died, but there are still many instructors who insist that to make a good pilot he must first be trained on an unstable machine before being allowed to go on a stable one, to make him careful; but, after all, *landing* is the great thing, and stable machines are just as hard to land as unstable. Personally, I am not at all sure that this is correct, and I believe that a pilot trained on stable machines from the start, after he has had about 30 hours' air experience, will be so confident and have such a good idea of what a machine ought to do in the air, that he will fly an unstable machine without even realizing its instability—that is to say, of course, if he has been properly taught. So far as engines go, it is only natural, through the demands of war, that we have been forced to use our obsolete engines for training purposes. As a matter of fact, these obsolete engines are just what are not required for training purposes, because being of an early type they are more liable to failure than the modern types, and engine failure is just what one wants to avoid in training. The output of the trade, however, has precluded the manufacture in numbers of a special training engine. But now that the obsolescent engines are of newer types, this difficulty will tend to disappear.

TECHNICAL AND MILITARY TRAINING.

Now to turn to the actual process of training. I will consider it under two heads—technical training both on the ground and in the air, and military training both on the ground and in the air. The first portion of technical training is the care of engines, rigging of aeroplanes, the use of the compass, the use of instruments and other such details. This is carried out at the two schools of military aeronautics; engines are taken down and erected and are run, samples of as many types as possible being provided to give the pupil wide experience. The same applies regarding the rigging and erection of aeroplanes, and pupils are made thoroughly conversant with the use of all the instruments. Thus a pupil before he actually learns to fly really has some knowledge of his engine, his machine and its instruments. He then goes on to preliminary and advanced training squadrons and continues to learn the enormous amount there is to learn on these heads by practical experience both in the air and in the squadron shops.

A very debatable point in the actual training in flying is whether reserve squadrons should train pupils all through—*i.e.*, from the very start up to the time they get their wings, or whether, as is the system at present, they do preliminary training with one reserve squadron and go on to higher training in another. There are certain arguments for and against both systems, but we have adopted the second. The greatest argument in favor of the first system is that the one instructor can take a pupil and really get to know him and follow him right through his training, but practically preliminary training takes a shorter time than advanced training, and the system of military training is simplified by separating preliminary flying training from the advanced flying training. One great advantage of placing preliminary training and advanced training in separate squadrons is that the squadrons can be homogeneous in equipment. So much for the technical training; it is fairly simple given a sound instructor and good weather.

I have already explained the many military qualifications demanded from the modern pilot, and the military training on the ground, like the technical, is carried out at the schools of military aeronautics where the pupil gets a good grounding in the use and care of the machine gun, wireless, artillery observation, photography and bomb dropping, and this training he completes from practical experience when he gets on flying instruction.

During his preliminary training in flying instruction, his military training is still theoretical and on the ground, but in the advanced training squadrons he begins to fly in formations and to drop bombs or their equivalent at a target. He carries out practical artillery observation by means of powder puffs on the ground which represent the bursting of shells, and he is sent out across the country to photograph various points in the neighborhood, and until he has proved himself efficient in all these operations he cannot be a qualified pilot. Fighting in the air is also practiced by various methods; two machines may be sent up to manœuvre against one another, both trying to attack, or the pupil is sent up whilst the instructor tries to attack him, or *vice versa,* or the instructor goes out and attacks a group of his pupils returning from a cross-country flight and so on.

FLYING AS A RECREATION.

I think I have made it fairly clear that training in aviation from the military point of view is getting more and more complicated, but I hope that I have also made it clear that actual flying from the practical point of view of getting from one place to another has become very easy and comparatively safe, and that, therefore in Peace everyone who can should take it up as a means of travel and a means of recreation. The great factor against aviation for such purposes is our uncertain climate, but with experience and with reliable engines it is possible to fly in almost any weather short of a thick fog, a hurricane or a violent thunderstorm. All these can be avoided by skill in navigation and a certain amount of weather wisdom.

I am always racking my brains for possible improvements in our system of training, and perhaps tonight I shall get some ideas. The only improvements I can think of at the moment are better qualified instructors and more of them, more reliable engines, and slower and more deliberate training, possibly including handling of the controls in an apparatus on the ground which will respond in much the same way as an aeroplane would in the air, but all these improvements are impossible to any extent during the stress of War, because the supply is forever trying to catch up the demand, and the demand is forever increasing both in numbers and quality. Sir Douglas Haig needs a certain fixed number of squadrons, and we must produce them or try to. In Peace we cut our coat according to our cloth.

THE BEST PILOTS.

The next point of interest to me is the actual study of the men who make the best pilots. The most unexpected people make good pilots, and very often the most promising ones never attain more than mediocrity in the air, and for this reason it has always seemed to me undesirable to lay down a stereotyped process of training. Personally I think that any sound man with sound nerves (and women, too, for that matter) can make a good, useful pilot, but it is only the exceptional individual who will make the really brilliant fighting pilot. Even the unsound; we have deaf people and people with wooden legs, etc.

There is always a great controversy as to the best age for flying, and as to the extreme age at which anybody can learn to fly. I think that there is no doubt that the best age to learn to fly is as young as possible, just as a boy learns to ride, but during War this is impossible, as the pupils would be too young to fight. We take a few below the age of 18 now, but, generally speaking, 18 is rather young for the great strain of active service, and I prefer the man of 20 to 25. When you come to the older category, I think everything depends on the life which the individual has led. A man of between 35 and 40 who has lived a hard life and is a good horseman will probably turn into a good pilot quicker than the man of from 25 to 30 who has spent his life in an office or doing nothing, but as a rule the older man will not stand the strain of active service fighting as long as the young man. The quality of horsemanship is quite a useful one in any would-be pilot. The requirements are just the same—good hands, a good head, steady nerves and judgment. Flying is perhaps a little easier than riding because you sit in a comfortable armchair in a quiet machine instead of on a slippery saddle on a very lively horse. Generally speaking, I think it is only youth that makes it possible to become a really star pilot who can do almost anything in the air without loss of nerve. Probably the young man of 18 to 25 makes the best fighting pilot, whereas the older man will do best on long reconnaissance and artillery work, where less dash and more experience and endurance are required.

Very much depends on the character and temperament of each man, and the ideal in training would be to teach almost every pupil somewhat differently, just as every young horse wants somewhat different handling to get the best results. The bold require holding back and the timid require pushing on. The fast learners want careful watching and the slow learners need infinite patience; so far as my experience goes almost an equal number of good pilots are produced from each of these categories.

A point of interest in this connection is the relative status of pilot and passenger, flying officer and observer. The Germans and ourselves are quite different. The Germans have a certain number of officer pilots, but a good many N.C.O.'s. Their observers are all officers and are supposed to take charge when in the air. As a rule, I think their observers very seldom become trained pilots.

In the Royal Flying Corps almost all pilots are officers—and the N.C.O.'s very soon get commissions if they do well—and the observers, although officers as a rule, are absolutely under the control of the pilot. Our observers, after a certain period of successful work in that capacity, are allowed to learn to fly, and usually make very good pilots. Two completely opposite theories, of which I think ours has proved to be the best. I think there are certainly cases where German N.C.O. pilots have shown cowardice and the officer observer has been unable to control them. Anyway, we go on with our system, and it works well, its only drawback being that we lose our observers just as they are getting really experienced—but experience is often equivalent to tiredness and caution.

QUESTION OF ACCIDENTS.

Another point of interest is the danger connected with training in flying. During Peace the first consideration was to avoid accidents, which roused foolish questions in the House, and in consequence delayed progress and wasted everyone's time. Since the War started, we have got away from that sort of nonsense, with the result that we take far greater risks than we used. In spite of this, the percentage of accidents has not really risen appreciably very much. A good many deaths are reported in the paper and frighten a certain number of people, but when you compare the number of deaths with the very large numbers of pupils in training and the very large number of hours in the air accomplished every day, the price is not great, and in the present stage of aviation the fact must be fearlessly accepted that no progress can be made without a certain cost in human life. When we return to Peace conditions, the ruling consideration will be the safety of the pupil, as practically all the other factors which govern us now will have vanished. We shall then be able to keep a man under training for a far longer period and take him much more slowly in the early stages, give him more instruction on the ground by means of various mechanical devices, and in fact render him almost immune from the ordinary accident. There is one very satisfactory feature in looking back through the accidents which have occurred since the beginning of the War in training—there have been extraordinarily few cases of breakage in the air, which speaks very well for British construction and inspection. The most common type of accident is engine failure, followed by an effort to turn sharply into a possible landing place and losing speed on the turn, which results in a dose-dive and serious smash. Even good and experienced pilots are prone to do this, and to me the only cure appears to be the avoidance of engine failure. This will assuredly come in Peace, when we can devote more energy towards real reliability in the engine instead of extreme lightness and exaggerated performances.

There are several points I want to hear your views on, for instance:—

Methods of training;
Size of aerodromes;
The value of the Maurice Farman;
Stable and unstable machines;
The division of preliminary from advanced training in flying;
Age and youth.

FINEST MATERIAL IN THE WORLD.

As an officer who has been responsible for training in the War Office now for four years, I feel that I have been wonderfully lucky in having the finest material in the world to work on both for instructors and pupils. The Englishman may be conservative, but he is certainly the finest pilot in the world; the value of all the old British characteristics which made us masters of the *Sea* is intensified in the *Air,* and they will make us masters of the air yet, in spite of our politics and our system of government, and all the many obstructions to progress which will assuredly spring up as soon as Peace is declared. War has been the making of British aviation, and we must look to it that we preserve and develop the fruits of this War so far as aviation is concerned. Now by technical training in the air I mean instruction in flying pure and simple, without any direct reference to its military uses. The best method of teaching flying is probably the most controversial point I shall touch on this evening; opinions differ enormously, and I am not going into a long dissertation on the subject, as I hope that some of you here will give us the benefit of your views at the end of the lecture.

During Peace a good many pilots learned to fly by the light of nature. They were just put into a machine and made to taxi about on the ground until they knew the controls, and then pushed off into the air, and left to take their chance—a thrilling moment both for themselves and their instructors. Now, I think it is fairly well established that dual control is an absolute necessity. It gets the pupil into proper habits in the early stages of his training, and this he cannot really dispense with unless he is a heaven-born genius who takes to the air as a duck does to water, and there are certainly some men who seem to require no training at all.

The most difficult part of flying is landing. Once off the ground and above any neighboring obstacles, flying is easy unless the engine gives out, or you meet very bad weather. The whole difficulty is to land safely. The most critical moment of a pupil's education is his first solo flight. I know one of my teachers always said that no one ever saw anything at all during his first two hours alone in the air. This was not quite true, but the feeling that you are up alone for the first time and have *got* to come down again is most alarming, and I've known cases where pupils have simply looked straight to their front and flown for many miles in a dead straight line until their petrol was finished and they had to land!

The stereotyped method of starting instruction is on a Maurice Farman, with a dual control, up and down "straight," gradually giving the pupil more and more control until he lands properly. In fact, nearly the whole art of flying lies in landing, and a man who lands well under any conditions will certainly be able to do anything else in the air well on his own initiative given a sound nerve. After the first few solos on an easy type of machine, the pupil usually returns to dual control on a faster and more efficient machine—after many and wearisome circuits and landing with dual control he is sent off on his first cross-country flight, another really thrilling experience. Before being allowed to do this, however, a pupil should be able to land within a marked chalk circle and his engine stopped from any height, and to have practiced landing slowly over obstacles.

Training by Instruments.

During this period of training one of the great bones of contention used to be the advisability of training a pupil to fly by means of his instruments as opposed to balance. Instruments used to be unrealiable. Instruments of late have become more and more reliable, and personally I am the greatest believer in using them for training. After a little experience with instruments as a guide, any intelligent man will find himself working without them instinctively, and they will have tided him over many dangers in the early stages. I have already talked about stability, and I think the day will come when an unstable machine will be looked upon as impossible. Another very interesting point is the value of air experience as a passenger before learning to fly. I did a good deal of flying as a passenger before I learned to fly, and I must say my own impression was that this air experience was invaluable. I am sure I learned far quicker in consequence of knowing exactly what was going to happen and exactly what cross-country flying was like. Our chairman, however, always says I am one of the worst pilots he has ever seen, so he will not agree.

I used always to be of opinion that a large amount of passenger flying would almost teach a man to fly before he was asked to touch the controls at all, but I have been somewhat disappointed in actual results. We get a good number of observers home from France for instruction in flying, and many of these have 150 to 200 hours' air experience. They certainly do learn quicker than the man without air experience as a rule, but the difference between them and their less experienced comrades is much less marked than I had expected. Why, I am still at a loss to understand, but certainly experience seems to prove that four or five hours' experience as a passenger is advisable and will probably hasten a pupil's progress in the early stages, but that any time beyond this is really not of much value.

Well, once the ice is broken by the first few cross-country flights, progress becomes rapid, and the pupil soon begins to really *handle* his machine in the air, and to practice real aerial gymnastics, such as steep spirals, loops, tail-slides, and so on. Then slowly the air habit begins to grow on the man, if he is ever going to be any good, and experience—and nothing else—makes it possible to land almost anywhere in a bad country with the engine stopped dead, and to drop faultlessly on to a strange landing place without any indication of the direction of the wind on the slope of the ground, and to manœuvre round and over storms, and find your way regardless of weather. As the pupil goes on, the best form of training is to force him to fly in really bad weather. There is nothing which gives so much confidence as a successful bout with a nasty day. Weather has extraordinarily little real effect on flying so long as it is sufficiently clear to see; fog and very heavy rain are the two really undefeatable factors in aviation. The War has taught us to laugh at weather. It is only four years ago that "bumps" were looked upon with the deepest reverence and respect, and there were certain crossings over the rivers and hills around Salisbury Plain which were usually avoided except by the boldest. Today, however, no one ever thinks of them, and yet almost the same machines are being used for preliminary training as were being used then. It is a very good example of the wonderful growth of confidence in the last few years, which has done much to push on the progress of aviation.

On the whole, flying itself is so easy that pupils suffer from over-confidence.—Careful teaching is essential, and very careful instructions as to the best method of meeting any emergency, such as a spin or a nose-dive, and it is only quite lately that we have had any authoritative statements as to how to compete with these situations, and even now there are probably people who differ as to the best course to follow if you find yourself nose-diving out of a cloud.

Anyway, the actual assimilation of the art of flying—or the Air-habit—is largely a matter of Air experience, and, given nerves and health and common-sense, there are very few Englishmen who won't make good pilots so long as they have sufficient experience.

The Discussion.

M. Jullerot said that he did not consider that dual control machines and box kites, etc., should be used for long in the instruction of the pupils, as they were quite different to the machines used for flying purposes, and it was impossible on them to get the proper range. With reference to instruments, he was dead against them in the beginning. The pupil looked at the instruments the whole time, and they were very often wrong, and in his opinion they should not be used until the pupil could fly properly without them; if they were used, it was better not to look at them. After seven years of flying he had now started using instruments, and he often found them wrong. They could not be used in very fast machines, and for the preliminary training he would rather not have any. Dual control is a necessity at the present time, as we have not time now to risk the other method. Dual control, with the seats arranged side by side, would be the ideal type of teaching machine. The British monoplane had given very good results. As regards the age for starting, he advised men should be unmarried, if possible unengaged—(laughter)—and of good heart. He stated that short-sightedness was not a bad thing, as it prevented people seeing too much. (Laughter and applause.)

Major Smith Barry said he would like to endorse what M. Jullerot had said about dual control. He would like to see it carried out more fully, and the pupil not being allowed to leave the ground until he had sat in the driver's seat. He thought there would be an economy of machines brought about by this, as only one type of machine would be required, and he thought six hours on one type with this method of teaching would be sufficient. He also thought that there should be a school of instructors and specialists who did nothing else, paid rather more or less than other people, and that they should be judged by the number of smashes and be held responsible for them. There should be none of these, except those due to engine failure. All should carry out the same views and teach in the same manner, and there would be more esprit de corps than exists at present. Teaching is now largely carried out by men home from France resting and waiting to go out again, and there was not the interest attached to the work that there should be, and this spirit was infused in those they taught. Where possible, where there is a two-seater and a scout of the same design, it would be a very good thing if the pupils could be trained on the two-seater before the scout.

Mr. A. V. Roe said he was in favor of the dual control machine, and he was of opinion that it was better for the flyer to be in front and the pupil behind; he then could watch the movements of the instructor with great ease.

Mr. Gordon England agreed with M. Jullerot that the side-by-side machine had very great possibilities. He had used one some years ago and he had found it almost possible to speak to the pupil while in the air, and with some types of people who forgot everything they had been told to do on the ground, this was of enormous advantage. He would like to be able to cut out and restore the control at will, but that at present all forms of control were complicated and unreliable. He thought it was bad for pupils to have instruments, and that it was better to learn to fly on sense alone, and not to bother about speed indicators.

Wing Commander Longmore said he did not believe in dual control. He had found it possible on the pusher type of machine to talk to the pupil, and if necessary to bash him on the head if he made a mistake. (Laughter.) He thought the pusher machine would give better results than the tractor, even though the pusher were bigger and harder to house and keep in trim. The pupils trained on a pusher could then go to a dual tractor, and then go by themselves and spend much time in the air in a moderately powerful tractor before going on to a scout school where they only use and fly scouts. He stated that seaplane instruction is very much the same as in an ordinary aeroplane. As regards instruments, he agreed with M. Jullerot and Mr. Gordon England. With reference to crowded aerodromes, he agreed with General Brancker, only he would put the number under instruction at 100; there were many narrow escapes on a misty or cloudy day flying at 2,000 or 1,500 feet.

General Brancker, in reply, said that instruments evidently seemed to be a very controversial point, but he still stuck to his own opinion on the point. Instruments needed to be looked after as much as engines. The idea of the two-seater side by side seemed well worth trying, but it must be remembered that at present they only had obsolescent flying machines used for teaching purposes. He thought Major Smith Barry was approaching the ideal in his remarks, which could not be done during the war.

Mr. White Smith moved a vote of thanks to General Brancker for his lecture, and Colonel O'Gorham to Commodore Paine for presiding. These were seconded and carried, and a very interesting and successful evening terminated.

THE CASE FOR THE LARGE AEROPLANE

By F. HANDLEY PAGE, A.F.Ae.S.*

THE question of aeroplane size is a most important one. It raises the whole question as to whether there is, or is not, a limitation to aeroplane size, and therefore whether progress in construction will be limited to improvement on present-day small types of machines, or whether there is an infinite possibility in the extension of designs to much larger types.

It has been argued by many that, just as ships, trains and other machines for transport purposes increase in size as years go on, so will the aeroplane progress, and that the larger aeroplane will have a definite place in the field of aviation. Others have adopted the opposite view.

The general consideration in favor of the large machine is that although there is a heavier initial capital outlay, large machines are much cheaper to build, cheaper to maintain and cheaper to run than small ones, and thus progress is seen in every type of mechanical transport towards the employment of larger and larger machines with a view to taking full advantage of the economies effected.

In an aeroplane there could, however, be no advantage in the use of large machines if that increase in size gives a disproportionate increase in weight which would more than nullify constructional advantages, or if the large aeroplane had aero-dynamical disadvantages. The whole case needs most careful examination from all points of view.

In the arguments set forth both below I have endeavored to compare machines of different size and review their relative advantages, determining first of all bases of comparison to enable a true picture to be obtained. As these necessitate the explanation of a new method of aero-dynamical composition I have set this forth at rather greater length than is necessary for the development of the argument proper. After a discussion of the aero-dynamical problem I have dealt with the effect on structural weight of an increase in the size of aeroplane, and then turned back to find the effect on the aeroplane's performance of the weight variation with size increase. Lastly, there are a few notes on the large machine from a flying standpoint. It is a matter of some difficulty to obtain a true basis of comparison from pilots' opinions. Pilots are, as General Brancker remarked in his paper, a very conservative body, opposed to innovation, and the machine of the moment's design is not necessarily the one of the future, or the one from which future machines will be developed.

Aerodynamical Bases of Comparison

To determine the calculated performance of any machine it is necessary to have available the wind-channel experiments on the Lift and Lift/Drag of a large number of planes as well as the resistance for various types of bodies similar to that proposed to be used. The curves of Lift and Lift/Drag are usually plotted in absolute units and in the form shown in Fig. 1.

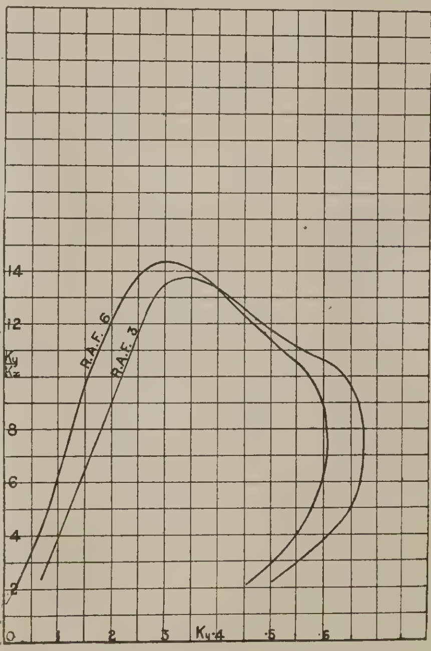

FIG. 1

From these wind-channel curves the performance of the whole machine is obtained.

After the general details of a machine's design are settled, such as the weight to be carried, the area of the planes, etc., the plane resistance at various speeds are found from the Lift and Lift-Drag curves. To these values are added the correct ones for body resistance, the values of the two curves added together and the total horsepower required calculated for different speeds. When the engine power and propeller efficiency is known, the curve of available horsepower can be plotted and the points of intersection of the two horsepower curves mark the limits of aeroplane speed variation.

It is quite easy to see that this method, although exceedingly useful for any particular aeroplane, does not afford a quick means of comparison between a machine with planes of different section or different shape or loading. I have therefore adopted a different method of plotting, so that the performance of any machine can be directly predicted from the wind-channel tests, on the Lift and Lift/Drag of the planes used, and on the body resistance, the new method taking into account the effect of altered loading or varying air densities at various heights.

I will deal first of all with the plane calculation.

The following is the notation adopted:

V —velocity of the aeroplane in ft./sec.
W —total weight in lbs. of the aeroplane.
A —area of main planes in sq. ft.
—density of the air in lbs./cu. ft.
g —32.2.
Ky—absolute value of the Lift Coefficient.
Kx—absolute value of the Drift Coefficient.
Rb—total body resistance in absolute units per ft. per sec. of the aeroplane considered —*i. e.*, resistance of the chassis, body, struts, in fact all the resistance of the aeroplane except that of the planes.

The following equations may be written:

$$W = Ky \cdot \frac{e}{g} \cdot A \cdot V^2 \quad \ldots \quad (1)$$

whence

$$V = \frac{1}{\sqrt{Ky}} \cdot \sqrt{\frac{W}{A} \cdot \frac{g}{e}} \quad \ldots\ldots \quad (2)$$

or

$$V = a \cdot \frac{1}{\sqrt{Ky}} \quad \ldots \quad (3)$$

The twin-motored Atlantic Aircraft Battleplane, with two Aeromarine motors.

---

* Lecture delivered before the Aeronautical Society on February 7, 1917.

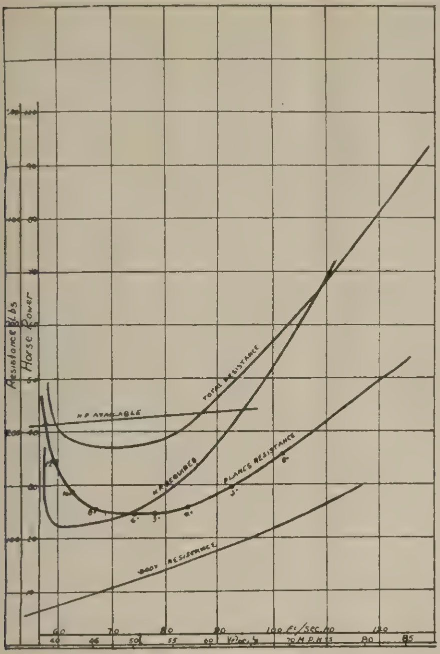

FIG 2

where

$$a = \sqrt{\frac{W}{A} \cdot \frac{g}{e}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

$$\text{Resistance} = Kx \cdot \frac{e}{g} \cdot A \cdot V^2 \quad . \quad . \quad . \quad . \quad (5)$$

$$\text{H.P.} = Kx \cdot \frac{e}{g} \cdot \frac{A}{550} \cdot V^3 \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Inserting the value of V from equation (2) above

$$\text{H.P.} = Kx \cdot \frac{e}{g} \cdot \frac{A}{550} \left(\frac{W}{A} \cdot \frac{g}{e}\right)^{\frac{3}{2}} \quad . \quad . \quad (7)$$

Whence

$$\text{H.P.} = \frac{Kx}{Ky}\sqrt{\frac{1}{Ky}} \cdot \frac{W}{550}\sqrt{\frac{W}{A} \cdot \frac{g}{c}} \quad . \quad . \quad . \quad (8)$$

or

$$\text{H.P.} = b \cdot \frac{Kx}{Ky}\sqrt{\frac{1}{Ky}} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Where

$$b = \frac{W}{550}\sqrt{\frac{W}{A} \cdot \frac{g}{e}} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

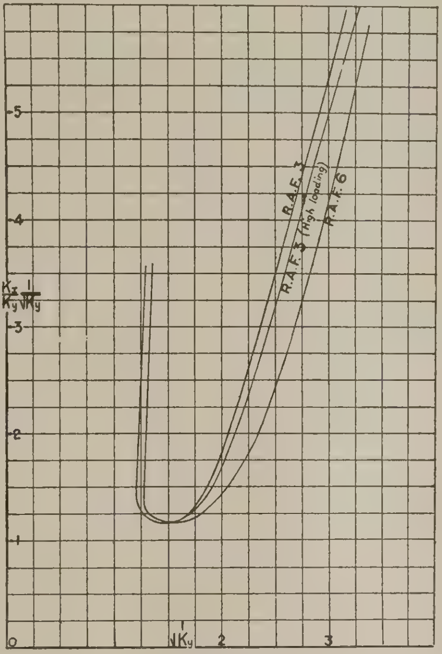

FIG. 3

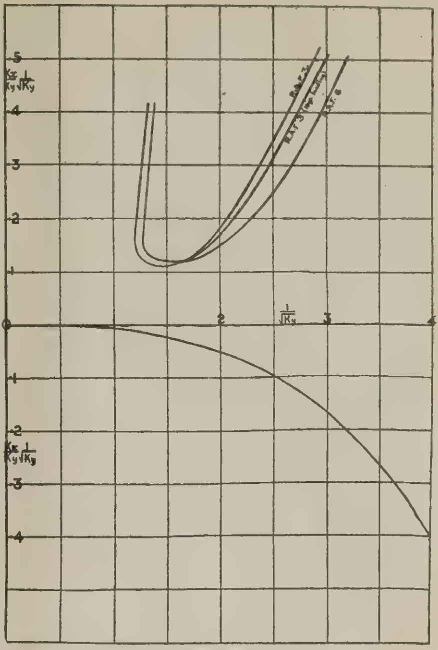

Summarising

FIG. 4

$$V = a\sqrt{\frac{1}{Ky}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\text{H.P.} = b\,\frac{Kx}{Ky}\sqrt{\frac{1}{Ky}} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Instead of the usual Kx and Ky curves for a plane there will now be plotted

$$\sqrt{\frac{1}{Ky}} \text{ and } \frac{Kx}{Ky}\sqrt{\frac{1}{Ky}}$$

which is equivalent to plotting h.p. required against velocities. A curve for the section known

FOREIGN NEWS

FRANCE

Paris, March 23.—A report current for the last three days that Sergt. J. R. McConnell, an American aviator with the French army is missing, has been confirmed. When last seen he was in battle with two big German aeroplanes.

McConnell and Edmund Genet, another American, went out on Monday over the lines of the retreating Germany army, McConnell flying lower than Genet. They met two two-seated German machines and the two Americans attacked them. Genet was slightly wounded in the face, and as the blood ran into his eyes he was forced to turn about.

Nothing has been heard of McConnell since. It is hoped he has landed and been taken prisoner. French machines sent out to see if the remains of his plane were visible reported that they could not see them. It is hoped that German aviators will drop the news of McConnell's fate on the French lines, as the airmen of each side usually do.

In a letter the correspondent of *The Sun* received yesterday from McConnell, written on Saturday, the American aviator told of a narrow escape on the previous day. Five American aviators of the Lafayette escadrille, of whom McConnell was one, flew twenty-four miles within the German lines, observing the villages burning in the area the enemy was evacuating.

The Americans were flying low, under 5,000 feet, and the German machine guns opened fire, using luminous bullets. As McConnell said, "I could see them passing my plane like a jet of water sparkling in the sunlight." McConnell got into a sharp fight with two German machines in which they managed to signal his range to their anti-aircraft batteries and duck away to escape the shrapnel. Shrapnel burst all around McConnell, who escaped untouched.

Two Americans, Hoskier and Genet, almost were in at the death of the German Zeppelin that was brought down at Compeigne. They were misdirected and steered north instead of south. The Americans got lost, as they reached a part of the country not covered by their maps, and landed thirty miles away. As they were four hours overdue, the escadrille feared they were lost until they returned.

Sergt. J. R. McConnell is a son of Judge S. P. McConnell, of Carthage, N. C., president of the Randolph and Cumberland Railroad. He is a graduate of the University of Virginia and at the time of his departure for France in the fall of 1914 was industrial agent for the railroad.

The March issue of *National Service,* the official monthly publication of the Training Camps Association of the United States, the organization of the Plattsburg men, publishes an article by the late Sergeant James R. McConnell. The article captioned, "The Day's Work of an American Airman on the Somme," probably was the last written by the daring flier.

"Yesterday," he writes, "was Christmas. The weather was too bad to fly in, but one pilot tried it and killed himself landing.

"As we and our guests sat down to our Diner de Noël (Christmas dinner), I noticed we were thirteen at table. I commented on it to Lieutenant de Laage, whom I was sitting next to. I explained that with thirteen at table it was supposed that one of the assembly would die within the year. He laughed. "'Well, it will hold good with this crowd,' he said, 'but unfortunately there will probably be more than one.'"

In another part of his article Sergeant McConnell said:

"As I write, a newly fledged birdman arrives at our escadrille, in the person of one Hoskier, from South Orange, N. J. He came to France seven months ago for the purpose of enlisting in aviation, and since then has raised the batting average of the Americans in the flying schools. The lieutenant calls me aside and asks me to explain to our newest addition the military deportment expected of him. It is the first time he has been at the front and, to be on the safe side, he punctuates his replies with 'Sir.'

"During the winter months the weather does not permit of much flying, but aviation has greatly developed in the last year and machines now fly under conditions which, twelve months ago, would have been considered a bar to aerial activity. As early as the summer of 1916 artillery regulating aeroplanes did work in the rain, traveling at times no higher than 400 feet. Avions de chasse were never called upon to go out in such weather. Also they never flew at night—it was thought impossible to land them. The fall of 1916 saw these swift, silver-colored fighting craft darting over the lines even when a canopy of mist would force them to stay under 500 feet, and taking the air on nights when moonlight brought only dimly into relief their landing ground. However, operations of this sort are very limited, for they serve little purpose."

GREAT BRITAIN

Private cablegrams received by John F. MacKay, publisher of *The Toronto Globe,* tell of a thrilling engagement in the air over the lines in Flanders, in which his son, Captain MacKay participated.

Captain MacKay is the youngest captain in the British Army and was with the British Aviation Squad "somewhere in Flanders." While flying over the German lines 5,000 feet up he was attacked from above by seven German aeroplanes, which opened fire on him. His observer was killed, Captain MacKay wounded, and part of the machine was shot away. To save himself, Captain MacKay reversed his aeroplane and made a vertical dive to earth of more than 3,000 feet.

He managed to right the machine just over the British lines and land safely. A bullet, which passed through his helmet, raised a lump on his head, but did not penetrate the skull.

He is now in a military hospital and cables to his father, saying he is well on the road to recovery.

Paris.—Vernon Castle, according to a correspondent of the *N. Y. Globe,* dancing man and air fighter, is in from the front for a few hours in Paris after a heroic experience in which cool courage saved his life for further service as a member of the British flying corps. As a part of his day's work he was ordered with three others, mounting single-seater fighting biplanes, upon a particularly dangerous mission over the enemy's lines.

Castle's machine was the target of a direct hit by an aircraft gun. The propeller and part of the rotating motor were shot away while the machine was at a low altitude, but he succeeded in landing unwounded just behind the British second line.

Clouds usually prevent reconnaissances from the air, because it is folly to fly at the low altitude necessary to move beneath them, which is the only way to see the ground. Consequently there is little air activity on cloudy days when the ceiling of the sky is 1,500 feet or less from the earth. Yet Mr. Castle and his brother airmen under these hazardous circumstances set out to obtain information of exceeding importance in connection with the British advance in the Ancre region.

While beneath the clouds at an altitude of 1,000 feet Castle became the target of a German "archie," or anti-aircraft gun. When he had recovered from the shock of the explosion, caused by a hit, he was almost directly over the German first line in a shower of bullets from rifles and machine guns. However, he glided to a safe landing on the shell-holed mud recently captured by the British. While the batteries were occupied with Castle, the two other airmen fulfilled the mission assigned to the party.

Recently another British airman met a fast German fighting machine above the clouds at a moment when, on account of a failing motor, he was about to return. Unable to maneuver on account of lack of power, the flier seemed an easy prey, but several German rapid fire volleys failed to hit a vital spot on the machine or its pilot. On account of the reduced power the British flier found it impossible to get the German in range of his gun. Realizing that it was only a question of time when he himself would be fatally hit, he determined to ram.

The next time the German approached firing from below the British machine was suddenly thrown into a steep dive with the machine gun rattling. Before the expected collision occurred the German pilot fell back in his seat. The Englishman avoided the crash by a few inches and both machines went to the ground back of the British lines, the German craft in flames. The victor, looking for his enemy's identification disk, saw seven wounds in the German's chest.

HOLLAND

A German aeroplane which flew over Sluis recently was shot at and hit by Dutch troops who were maneuvering in the neighborhood, according to the *Handelsblad.*

The aviator was wounded and compelled to descend in Dutch territory, but before he could be overtaken by the Dutch soldiers, he restarted his machine and flew three hundred meters over the border into Belgium.

German troops hurried to his rescue and he was carried away by Red Cross attendants.

Sluis is situated on the Belgium-Holland border, ten miles northeast of Bruges.

JAPAN

The following are from the *Kobe Chronicle* just received:

Thursday, February 15.—One of the military aviators who arrived at Kofu from Tokorozawa on Monday (12th instant) started on his flight over the high mountains of Koshu and Shinshu provinces to Lake Suwa. The aviator, however, encountered strong adverse winds between Yakegatake and Komagatake and finding further progress impossible, had to return to Kofu. The flight for the day was abandoned.

The flight over the mountains had to be abandoned again yesterday owing to unfavorable weather.

Friday, February 16.—After forced idleness for two days at Kofu owing to unfavorable weather conditions, Lieutenants Makabe and Takikawa left Kofu on the 15th instant at 7:30 A. M. and, successfully negotiating the high mountains standing between Kofu and their destination, safely arrived at Suwa. After encircling the frozen lake several times the aviators alighted on the ice, where a large number of people had assembled to welcome the arrival of the aviators.

February 14.—A new aviation college has been established by Mr. Tamai Seitaro at Haneda, near Kawasaki, midway between Tokyo and Yokohama. Mr. Tamai has secured a large field containing 300,000 *tsubo* from Viscount Ijuin, and has built a school and dormitory buildings. Ten students have enrolled in the school and the formal opening of the college will be held April 1. The term of the school is three months and the tuition for the term is 200 yen.—From *Japan* ***Advertiser.***

Scale Models

In these times with compressed air and gasoline motors available for use in model aeroplanes, model flyers are showing greater inclination to the construction of scale models of large machines through the use of which, it has been proven, greater results can be obtained from a scientific and educational standpoint. At the aeronautic exposition scale models of Curtiss, L. W. F. Nieuport and various other types of successful machines were on exhibition, but the most promising of all for actual results was the model monoplane equipped with a one-half horsepower gasoline engine constructed by Mr. Young, of Mineola, Long Island, N. Y. Mr. Young stated that on several occasions good flights were made, but with a few modifications and changes he contends that even better results are possible.

Achievements along these lines are not entirely due to the ing of all for actual results was the model monoplane equipped reports that have appeared in Aerial Age western model flyers have shown a tendency toward the construction of scale models to be driven by compressed air or gasoline engines instead of rubber strands.

Perhaps the foremost of western model flyers interested in the development of the mechanical driven scale model are Mr. Henry Rompel, Kansas City, Mo.; Mr. William Kohler, Los Angeles, Cal., and C. Otis Dumm, Boulder, Colo., whose photograph was reproduced in our issue of October 9th, 1916. Mr. Dumm is responsible for the construction of at least two dozen scale models of prominent aeroplanes. In our issue of December 25th descriptions and photographs were reproduced showing the rotary gas engine and scale model constructed by Mr. Henry Rompel, and in a forthcoming issue a photograph and description of Mr. William Kohler's gas engine-driven monoplane will appear.

From a standpoint of recreation and a minor knowledge of aeronautics the rubber strand A type model has proven itself to be a suitable medium. But on the other hand, if a more comprehensive knowledge of the principles of aeronautics is desired, there is but little doubt but that the engine driven scale model affords the most satisfactory means to realize this desire. Although the number of those now engaged in the development of efficient scale models is small, there is ample reason to believe that the time is not far distant when the majority of model flyers will devote their entire attention to the more efficient method of acquainting themselves with the fundamental principles of the aeroplane. The results of those whose activities have already been announced is evidence of this fact.

A Scale Model of a Nieuport Monoplane

The model of the Nieuport monoplane herewith described was constructed by Mr. Otis Dumm, Boulder, Colo., and is perhaps the most perfect of all the models in his collection. The model was constructed as near to scale as is possible and represents a splendid example of good workmanship. Although the model is not capable of flying, there is little doubt but that it could be adjusted as to enable the installation of a compressed air motor.

The wing spread from tip to tip is 52½ inches, the length of the model being 39⅛ inches overall. It is fitted with standard Nieuport system of control, wing warping by foot, with a single lever for rudder and elevators. The ribs are each different in shape and are built up of 1-16 by 3-16-inch spruce. The main spars are ⅝-inch thick by ¼-inch wide at the center and taper to both body and tip, thus producing a true Nieuport curve and chamber for each rib. A four strand cable is used for the bracing of the wings, two strand cables being used for the control wires, all of which are tightened with turnbuckles. The cowles are made of aluminum as is also the front.

Oval brass tubing ⅛ by ⅜-inch is employed in the construction of the undercarriage with a real stout laminated leaf spring and two 2½-inch rubber tired wire wheels. The model contains a seat for observer as well as pilot imitation leather being used for upholstery. The edge of the cockpit is likewise upholstered with imitation leather. Spruce ¼ by 3-16-inch is used throughout the body of the machine. The controls are made to operate similar to those of a large machine.

A 12-inch laminated propeller is used in connection with the model, the propeller having been made up of ten sections of wood in the following proportions: four mahogany, two white oak, two birch and two maple.

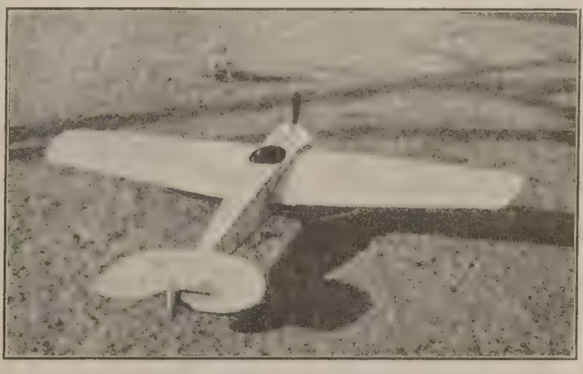
Perhaps one of the most interesting features of the model is the imitation engine. The miniature engine is of the Gnome type and is mounted in the cowl of the machine. The entire engine is made from hard wood even to the valve stems, rockers and radiating pins to which the cylinders are joined. An electric motor is situated behind the engine and is used to revolve the engine and propeller to produce a real effect. The chassis is enameled black, the entire covering of the machine being coated with varnish and shellac.

Following the Nieuport fashion the turnbuckles are fastened to heavy tin clamps to the wing spars. The warping wires are confined in brass tubes of 1-16-inch outside diameter.

The machine complete weighs but 3½ pounds and was built to a scale of 1½ inches = 1 foot.

The small machine shown in the photograph was made after the design of the large machine and is scaled ¾-inch = 1 foot. The body and wings of the small machine are made of cardboard covered with cheesecloth wood of ⅛-inch dimensions being used for the landing chassis and spars.

In addition to being president Mr. Dumm is perhaps one of the most active members of the Boulder Model Aeroplane Club which promises to be a very active club.



Large and small Nieuport models made by Mr. O. Dumm.

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Calling on a Motor Manufacturer

On Octember 87th, 1919, we took the train to Powerhorse, N. Y., to interview the designer of that great motor, the Rabid Radial Rotary. We had been warned that he was an exceedingly hard man to interview, very modest for one of such genius. However, we have never failed in an interview yet, so we decided to take a chance. To make a long story a little longer and to fill up space we will proceed. We arrived at Powerhorse, and immediately went to the Rabid Rotary Factory. One could see it from a great distance, and hear the throbbing hum of the workmen chewing gum, mingled with the sound of the rest drinking soup at their noon lunch hour. We approached the factory, opened the door, entered, and were promptly thrown out by the watchman. However, upon explaining our purpose he apologized and let us in. We gave our card to a man standing there and directed him to take it to Mr. I. M. Boranstroke, the inventor of the engine. He hurried away, and came back in a half hour. (The factory was so large that it took two men a half hour to walk its length. Question for mathematical readers. How long would it take three men, and why?)

We were ushered into Mr. Boranstroke's presence, and took a chair. (And a cigar from the humidor by the table). We decided that we would open the conversation, and wishing to make a particularly apt remark we said, "Well, sir, nice weather we're having."

The famous man looked out of the window and said, "My motor is the most wonderful that has ever been devised. In fact it beats a lot of motors that have only been imagined."

Ah, now I had him started!

"Mr. Boranstorke," I parried, "Would you mind telling me something about your motor and what your plans are for its marketing?"

The great man paused, mopped his brow, and breathed heavily. We could see that he was undergoing some very tremendous emotion, and that his reply would be of great importance to the motor world in general. Finally he opened his mouth.

"Yes," he gasped.

"Ah, you will tell me," I returned.

"You asked me would I *mind* telling you," he said, "and the answer is *'yes.'* Luke!"

And they threw me out in the cold, cold night.

But the report was handed in to the boss follows:

"When interviewed by our rising young reporter, Mr. I. M. Boranstroke gave out the following specification of his motor.

Pistons. Twelve.
Cylinders. Ditto.
Bore. 48 calibre.
Stroke. 35 a minute.
Revolutions. See Russian History.
Weight. Quite light.
Price. Never sold one.

(*Note. The writer of the above article has been discharged.* —Aeronitis Editor).

Puerile Poems

Dmirsky was a pilot
In the Army of the Czar,
But falling from his aeroplane
His features he did mzar.
(*Hint—The Z is silent.*)

After deep thought, we have hit upon a way of punishing the "Little group of willful men." Put the whole crew of them in a Zeppelin and send them on a raid over London.

Under the title "A Contribution to Science and Literature," *Aeronautics* (London) prints the following:

"Full many are the controversies that have raged anent the precise method whereby we destroy Zeppelins. The censorship unhappily forbids us to reveal in the detail the means utilized for this purpose; but in Japan, if we are to believe the *Daily Express,* they are more fortunate in this respect; for a peripatetic Japanese officer contributes to our contemporary the following accurate description of the means whereby we secure the country's defense against aerial attack.

"Two more Zeppelins to fall in Essex County. That extreme best news make all Kyoto most glad. 'Very soon' friend remark upon me, 'German Zeppelin will know it is the certain deaths to make air raid on England. Then air excursions are to stop.'

"England's air defense is nearly perfect to the present. When Zeppelin come to England only one thing is to do. Turn on all searchlight on Zeppelins. Then make gun fire upon them until Zeppelin full with holes. This is what happen then. English aeroplanes make chase upon German airships, but latter is full with gun holes, therefore most impossibility for Zeppelin to rise in clouds. What happen? Honorable Great Britain aeroplane makes descent upon Zeppelin, then latter fall in flame and crew becomes deadish. This is Japan idea how to make destructions on air raiders.

"We have to thank the writer of this illuminating revelation not only for his contribution to the history of aerial service by his convincing explanation of the manner in which a Zeppelin can best be brought down, but also for enriching the English language with the picturesque and descriptive word 'Deadish' which, we hope, will live."

If we may be permitted to interject a word here, we may say that we slightly suspect the editor of *Aeronautics* of having read our Hashimura Togo.

(*Continued from page* 81)

as R.A.F.6 and one for the section known as R.A.F.3 have been plotted out in this way. It is well to examine these curves to see their general application before proceeding to deal with the question of plane comparison. In Fig. 4 are plotted the ordinary Kx and Ky curves for R.A.F.6 and R.A.F.3. R.A.F.6 has the lower value of Ky maximum and higher value for Ky/Kx. The maximum value of Ky for R.A.F.6 is ·605, and that of R.A.F.3 is ·695. The result of this is reflected in the curves in Fig. 3 where R.A.F.3 gives a slower landing speed than R.A.F.6 for the same loading. The slow speeds are related in the ratio of the sq. root of their maximum Ky or in the ratio of 1 to 105. These plotted curves give them the relationship between h.p. and velocity for equal loading. If it is desired to know the actual speeds obtained with different h.p. or in effect to obtain the correct scale for these curves it is only necessary to obtain the multiplying factor, converting the horizontal scale into feet per second and the vertical scale into h.p. This is done by evaluating the constants a and b in equations 4 and 10 above, inserting therein the correct valuation of W, A and e/g.

(*To be continued*)

What the Army Lacks

(Editorial in the Chester, Pa., Times)

To day we lack, in round figures, about 2,000 aeroplanes, 25 dirigibles and 150 observation balloons to make this country seventh in aeronautic equipment for aeronautic defense. We have only about 100 trained military aviators, and plans to train about 400 more. Yet the aviation section of the American Signal Corps has received about 1,400 applications from candidates. There is no dearth of men competent to fly and willing to learn; only the machines and equipment are missing, and that is now being supplied as rapidly as possible.

Germany at present has over 9,000 aviators and about 20,000 machines in daily use in the war zone, and she is building machines to carry fifteen tons, equipped with high speed motors of 300 horsepower. England has 107 aviation and kite balloon training schools and is rapidly drawing near her plans to have 10,000 aeroplanes in service. In the Royal Flying Corps there are all told 100,000 men, including officers, aviators, gunners, mechanics, repair men and others connected with the business of flying.

According to Alan R. Hawley, Henry Woodhouse, and military men qualified to know whereof they speak, the United States needs at once 2,000 trained pilots with a ratio of three machines to each pilot, which proportion has been found most practical in Europe. Of course this is to obviate delays caused by breakages and overhandling.

At present we have not a single dirigible in operation in the United States service. America is not, however, without patriotism among her aviators and ship builders, and several patriotic concerns have expressed their willingness to undertake the work at cost. Among these concerns are ship builders, used to hurry orders, and with nearly all the necessary factors at their command.

Airplane manufacturers, engineers, draftsmen, etc., are requested to send us their names for our catalog mailing list.

Supplementary data sheets will be issued frequently specifying additional parts which we are prepared to furnish.

Burgess Training Hydroairplane

Among the many models of Airplanes, Seaplanes and Flying Boats produced by this company the new "U" type Hydroairplane meets a very pressing need—an efficient, well-balanced flying machine of conventional type and low power for militia training purposes.

The Massachusetts Naval Militia has the first one now in service.

Standard Deperdussin control in duplicate; Curtiss OXX-2 motor; simple float; light, sturdy construction; large speed range (forty to sixty-eight miles per hour); are characteristics necessary to the hard service required for training purposes.

Hydroplanes and pontoons designed and manufactured for airplanes of every type, including Curtiss, Sturtevant and other makers.

Designers and constructors for the U. S. Army and Navy and British Admiralty.

Above All:--Strength

The knowledge of strength engenders confidence, and the direct result of confidence is the will and power to excel. No matter from what angle we consider the aeroplane and the dirigible, STRENGTH is of paramount importance, completely overshadowing other characteristics of the machines of the air.

It is but common knowledge that a chain is as strong as its weakest link, and it is not stretching the point to say that the aeroplane is efficient, strong and sturdy as its fittings and special parts.

STRENGTH, however, is not mere bulk, brute power, or weight. Anyone could build strong fittings,—but the fittings would undoubtedly be far too heavy for the modern machine. Strength, then, in the aeroplane, must be the result of scientific research, absolutely the finest of materials, and *hairline precision.*

ACCURACY can result only from long experience at a task, and conscientious adherence to the scrupulous performance of it.

SERVICE is obtained in direct proportion to the knowledge, skill, materials,—and *conscience* put into the manufacture of a product.

The Erie Specialty Company is now supplying Screw Machine Products and Aluminum Castings to the leading aeroplane companies:—the aeroplane companies which desire the finest fittings and special parts that modern science and skill can produce.

Every part that leaves the factory of the Erie Specialty Company is tried, tested, and proved perfect.

We shall be glad to hear from those manufacturers of aircraft whose desire is for Screw Machine Products and Aluminum Castings which are accurate, strong, and efficient. Tell us your requirements and we will submit estimates and early delivery dates.

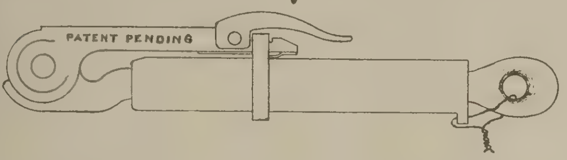
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

For Your Flying Boats Use

Adopted by the U. S. Aeronautical and War Departments.

All the prominent builders of flying boats use this glue in combination with linen between the veneer of the diagonal planking on all their flying boats, pontoons and floats. It is not only waterproof and elastic but will waterproof and preserve the linen indefinitely. Experience has shown that when this glue is used, owing to its elasticity, the inside layer of diagonal planking will remain perfectly water tight although the outside layer may be badly broken.

CYLINDER HEADS

The aluminum cylinder heads of the Sturtevant Aeronautical Engine are completely water-cooled with ample passages for unobstructed circulation of the cooling water around the valves. Cast iron valve seats are employed.

Overheated valves are an unknown trouble in the Sturtevant engine.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

Thoroughness is the distinguishing element in the making of a Hess-Bright Ball Bearing. Can you imagine an entire organization keyed up to that close attention to detail, that "infinite capacity for taking pains" which some one has said is the true cause of genius?

You will find the Hess-Bright Manufacturing Company to be such an organization. You will find the Hess-Bright Ball Bearings to be of the quality which can only result in the product of such an organization.

Hess-Bright's Conrad Patents are thoroughly adjudicated

Equipped With
Ackerman Wheels

"IT'S IN THE SPOKES"

AFTER four years' exhaustive tests, The Ackerman Wheel Company offers to aeroplane builders a wheel of special design that will solve many of the difficulties hitherto encountered.

In a series of laboratory tests (see illustrations below) the wheel was attached to a large case, into which was loaded 1,500 pounds of sand. A side thrust blow, with the wheel seven feet removed from the point of contact, was calculated to give the wheel a stress of 27,000 pounds. This was when the wheel struck the plain floor surface. To test the wheel to its maximum, two cleats of wood were nailed to the floor, four inches in advance of the striking point, and under this test four spokes of the wheel were broken. Calculation showed that the energy of the blow totalled 49,800 pounds.

A special alloy, specially treated, is used to meet all conditions that the wheel can be subjected to. The steel receives a special process in the treating, so that it will give the required resiliency, starting at the center of the curve and gradually growing stiffer and stronger both to the hub and relative to the structure of the spoke. The spokes being made on the curve, they are hung on the hinge at the rim, being a unit in the hub, allowing them to open and shut according to the load placed on the hub.

In the aeroplane wheel it is found that the hub will leave the center four inches when maximum loaded, and return to center as load is decreased, without the springs taking a set. There has never before been a wheel invented which would meet any such conditions.

These wheels can be built according to size and weight of any load from 500 pounds up to 5 tons

"2,000 AVIATORS BY DECEMBER AND AIR MINISTRY" MOTTO OF AERO CLUB OF AMERICA'S ANNUAL BANQUET WHICH WAS ENTHUSIASTIC RALLY FOR NATIONAL PREPAREDNESS

WITH "two thousand military aviators by December," the eleventh annual banquet of the Aero Club of America turned into an enthusiastic rally for national preparedness which resulted not only in adding impetus to the movement for aerial preparedness but also to the presentation by Rodman Wanamaker of an armed air cruiser and a fully equipped aerial coast patrol station for the aerial protection of New York.

Close to six hundred people attended the banquet, which was held at the Waldorf-Astoria Hotel on March 30th.

Mr. Alan R. Hawley, president of the Aero Club of America, presided and Mr. Henry A. Wise Wood, chairman of the National Advisory Committee on Aeronautics, was toastmaster. The speakers included Hon. James W. Gerard, former Ambassador to Germany; Major General Leonard Wood, U. S. A.; Rear Admiral Robert E. Peary, chairman of the National Aerial Coast Patrol Commission, Mr. Stephane Lauzanne, editor of the Paris *Le Matin*; Congressman Murray Hulbert, Major Carl F. Hartmann, Signal Officer, Eastern Department, U. S. A.; Henry Woodhouse, member Board of Governors, Aero Club of America, and Godfrey L. Cabot, president, Aero Club of New England.

Mme. Geraldine Farrar sang the "Star Spangled Banner" during the standing toast to the Commanding Chief of our Army and Navy.

Other guests besides the speakers at the guests' table were: Henry B. Joy, vice president, Navy League; Hon. Thomas D. McCarthy, George W. Dunham, president, Society of Automotive Engineers; Commander Charles L. Poor, New York Naval Militia; Lieut. L. V. D. Herbster, U. S. N.; Elmer A. Sperry, Evert Janson Wendell, Robert Bacon, president of the National Security League, Glenn H. Curtiss, August Belmont, F. L. V. Hoppin, W. W. Niles, Col. I. N. Lewis, U. S. A.; W. W. Miller, William Berri, Captain Robert A. Bartlett, Cortland Field Bishop, Maurice Leon and Augustus Post. Telegrams and messages were received from many representative national defense workers and authorities, including Secretary of the Navy Daniels, Orville Wright, Senator Tillman and others.

Theodore Roosevelt said, among other things: "Believe me, I appreciate what the Aero Club is doing."

Senator Benjamin R. Tillman, chairman, Committee on Naval Affairs, United States Senate, wrote:

"Tell the assembled guests that America, in a very solemn hour of her history, expects every man to do his duty—and that she knows the airmen will not disappoint her. The men who will be sitting around the banquet table are the brothers of the Rockwells and others who have made the American name a symbol for daring in France, and if America calls, we know that they will render her yeoman service. Long live the Aero Club!"

Mayor Mitchel wrote:

"I am entirely in sympathy with the purposes of the club."

Second Assistant Postmaster General Otto Praeger wrote:

"It would be difficult to exaggerate the importance of the work which the Aero Club of America is doing in behalf of aviation, and I shall always be glad to render any possible assistance to the club in its laudable efforts."

Brigadier General R. K. Evans, U. S. A., sent a message from San Francisco, reading:

"I take great pride and pleasure in my connection with the Aero Club, and the little I have been able to do to assist in its work. I am glad to say that I believe that the Aero Club has accomplished its work towards preparedness with more thoroughness and completeness than any other instrumentality in the entire proposition, since we partially awoke to the fact that the United States is an unarmed and defenseless croesus in a world of hungry, fully armed and organized bandits. I expect to go into camp permanently in Washington, next October; and I hope then to do my 'bit,' as the Britisher says, in helping along the great work to which our club has given its heart and mind, with such eminent success."

Governor Charles B. Whitman, of New York, wired as follows:

"I am deeply appreciative of the work of this organization. Under modern military conditions the development of aeronautics is of vital importance to the defense of the nation."

Charles D. Walcott, chairman of the National Advisory Committee on Aeronautics, who expected to be present but was held in Washington by the present business connected with developing the air services, in his telegram advised the club to *"urge most strongly aerological surveys over North America and adjoining waters for the protection of lives of aviators, safety of aircraft and efficiency of action. At present practically nothing is known of the movement of the fluid in which shortly thousands of aircraft, representing millions of investment and more important, thousands of trained exceptional men will be operating."*

Emerson McMillin, the New York banker, who served in the Civil War with five of his brothers, and has spent $300,000 to develop national preparedness, in his communication, copy of which is enclosed herewith, praises the Aero Club of America for its "indefatigable and efficient work for national defense," criticizes the muzzling of Rear Admiral Bradley A. Fiske, who was not present at the banquet having been forbidden by Secretary of the Navy Daniels to address the gathering, and concludes quoting the following sentence of an editorial from one of the metropolitan papers.

"Under existing conditions, Daniels is a crime, and Baker is a blunder."

Congressman Charles Pope Caldwell telegraphed as follows:

"I am actively engaged in the preparation of a bill to create a department of the air headed by a secretary who is to be a member of the Cabinet. It is my belief that the war will be determined by the effectiveness of the aircraft and we of America who were the pioneers in this art should be the first as a power. In this respect the Aero Club of America has done much to awaken the country to this situation, and I trust they will continue the good work and assure you of my desire to cooperate with you."

Howard E. Coffin, a governor of the Aero Club of America and member of the Council of National Defense, wired as follows:

"I desire to congratulate the club upon its share in the development of aeronautics during the past year and impress upon our members the seriousness of the need for the most active and sincere cooperation, both with the military departments and with the newly formed Manufacturers' Association. The influence of the Advisory Commission of the Council of National Defense will be exerted in favor of the adoption of a three year construction programme with a definite assignment to each manufacturer of his part in the work. We must have standardization so far as possible in materials and in the details of design, and the number of models assigned to each factory must be reduced to a mini-

mum, it is only through a proper classification and concentration of our industrial resources in this industry that we may hope to make definite progress in this art so vitally necessary in the defense of this nation.”

Assistant Secretary of the Treasury Bryon R. Newton's message reads as follows:

“I had hoped to be present and offer a word of congratulation to the members of the grand old Aero Club who have accomplished so much, and from whom so much is yet expected at this time when activities in the air are of such immeasurable importance to the nation. How marvelously our dreams have been realized and exceeded in the past decade! Ten years ago you and I were wild with enthusiasm when we saw Henry Farnum make his old biplane leap a distance of three hundred feet down at Asbury Park. Only five years ago we were bewailing the fates because our Government would not give material recognition or support to aviation. Today we have millions available for the purchase of aircraft and find ourselves unprepared to supply the machines and the aviators that are needed. From now on the Aero Club of America, more than ever before, must play an important part in stimulating and accelerating this important task of preparedness. I congratulate you on the fine work the club has done, and my best wishes and hearty cooperation go with you in the future.”

Recently Commodore R. P. Forshew, commanding the Naval Militia of New York, advised the club that he had asked the Navy Department to train two officers of the Naval Militia in aviation. The Navy Department answered that the naval aeronautic school at Pensacola is full and these officers could not be trained. Commodore Forshew appealed to the Aero Club of America for assistance and Mr. Hawley made an appeal for funds at a meeting of the National Special Aid Society, which resulted in raising $800. Commodore Forshew, in regretting that he could not attend the banquet, wrote:

“The money for the training of the two officers at the Curtiss Flying School was received from the National Special Aid Society promptly following your request. This is but another instance of the assistance which your club has given to the Naval Militia in its aeronautical work, all of which has been greatly appreciated. More power to you.”

Mr. Hawley proposed a toast “To our Country,” which was responded to by the assembled guests.

He then addressed the members of the Aero Club of America, the Automobile Club of America, the Society of Automotive Engineers and the guests, and welcomed them to the eleventh and largest dinner ever held by the Areo Club.

He said, in part:

“The club has accomplished more in the past year than in any two other years in its history. In 1916, through its efforts, the Army and Navy appropriations for aeronautics were raised from $3,000,000 to $18,000,000. To accomplish this two million pieces of literature were distributed and 200,000 letters dealing with facts were prepared.

“A few weeks ago the First Pan-American Exposition exclusively for aeronautics was held, and was a success from every standpoint. Governor Whitman opened the exposition, and club members were greatly pleased with the tribute paid the club when he said:

“ ‘The preparedness we now possess is due to the determined insistence of a minority. And not the *least* of the forces that have fought for the wise thing, reading the future with clearer vision than their fellows, has been the Aero Club of America. Its task has not been easy, for of my own knowledge I know that its progress has been blocked by every misunderstanding, but never at any time has there been a hint of discouragement; any cessation of dynamic effort. And if no other result has been achieved, the existence of the Aero Club would be justified by this exposition that now gathers and directs not only the aeronautical genius of the United States but of our sister republics.’

“You all know of the club's many activities and I will not speak about them now.

“The Collier Trophy Committee unanimously recommends that the Collier Trophy for the year 1916 be awarded to Elmer A. Sperry and Lawrence B. Sperry for the development and demonstration of the Sperry drift indicator.”

Sperry Awarded Collier Trophy

Mr. Hawley then announced the award of the Collier Trophy, which is awarded annually for the greatest achievement in aviation in America, the value of which has been demonstrated by use during the preceding year, to Mr. Elmer A. Sperry and Lawrence B. Sperry for the development and the demonstration of the Sperry drift indicator.

Medals of Merit Awarded

Mr. Hawley also announced the award of the Aero Club of America's medal of merit as follows:

To Miss Ruth Law, American distance record cross country, November 19, 1916, 512,123 miles.

Philip A. Carroll, for his patriotic work in training military aviators at Governor's Island, 1916.

Floyd Smith, American hydro altitude records: January 12, 1916, one passenger, 12,333 feet; January 11, 1916, two passengers, 9,524 feet; February 15, 1916, three passengers, 9,603 feet.

Corporal A. D. Smith, U. S. A., American hydro duration record, Feb. 19, 1916, 8 hrs. 42 mins.

Captain C. C. Culver, U. S. A., for wireless experimentation, 1916.

James V. Martin, for the invention of the aerodynamic stabilizer.

Aerial Coast Patrol Unit No. 1, for its pioneer work in developing aerial coast defense.

In recognition of aviation service rendered at the Mexican Border, 1916: Major B. D. Foulois, Capt. J. E. Carberry, Capt. W. C. Kilner, Capt. Ira D. Rader, Capt. C. C. Chapman, Capt. H. A. Dargue, Capt. R. H. Willis, Capt. T. S. Bowen, Capt. E. S. Gorrell, Capt. A. R. Christie, Capt. T. S. Dodd, U. S. A.

Victor Carlstrom, three additional bars to Medal of Merit he already holds.

American Altitude Records:
April 30, 1916, one pasenger, 16,225 ft.
April 10, 1916, two pasengers, 11,180 ft.
American Distance Cross Country Record:
May 20, 1916, one passenger, 283.02 miles.
Winning of the Curtiss Marine Flying Trophy for 1916.

T. C. Macauley, three additional bars to Medal of Merit he already holds for:

American Distance—Closed Circuit Record:
May 4, 1916, five pasengers, 154.08 miles.
American Hydro Altitude Records:
May 4, 1916, five passengers, 775 ft.
April 30, 1916, six passengers, 875 ft.
American Hydro Duration Record:
May 4, 1916, five passengers, 2 hrs. 23 min.

Ambassador Gerard Praises the Aero Club's Work and Points Out Need of Aerial Preparedness

Ambassador Gerard said, in part:

I am not used to making speeches. For the last two years I have been trying to keep three things, peace, silence and my temper. Besides, I rather sympathize with the Prussian General who said that he preferred taking a thousand yards of trenches to making a speech.

You gentlemen in the Aero Club are to be especially congratulated at this time because of the work you are doing, not only missionary, but actual. You have provided training for one hundred aviators in the last eighteen months.

What use is a man in a street fight who has no eyes. What use is an army, however well equipped and drilled without a modern Army's eyes—its aviators.

Modern war is largely a matter of mechanics and munitions.

Nevertheless we hear even to-day prattlings about embattled farmers taking their old muskets from over the chimney piece and defeating the invader. But nowadays the old flint-lock means Zeppelins, aeroplanes, captive observation balloons, steel helmets, gas and gas masks, machine guns, searchlights, sixteen-inch guns and eighteen-inch howitzers, trench mortars, range finders, telescopes, armored automobiles, tanks, miles of barbed wire, underground mining, rockets and grenades and countless other instruments of war, the proper use of which can only be learned after years of hard application.

The legend of the embattled farmer is responsible for much unpreparedness. Suppose the embattled farmers were called to war hurrying armed with squirrel rifles (whatever that means) in their Ford flivvers to repel the invaders.

Why, before they even sighted the enemy they would be bombed by planes and Zeppelins, gased, hammered with trommel fire, while a curtain of fire in their rear prevented their escape—from fifteen miles sixteen-inch guns would pound them to jelly—the embattled ones would never see the infantry of the foe.

All these modern means of war require great preparation. And in the most important—the primary branch of aviation **you of the Aero Club of America have gallantly taken the lead. The whole country is grateful to you.”**

Besides the gentlemen already mentioned there were present practically all the aeronautic authorities.

Rodman Wanamaker Presents Large Air Cruiser for Aerial Defense of New York—August Belmont Presents a Paul Schmidt Hydroaeroplane

Mr. Hawley read Mr. Rodman Wanamaker's letter offering a large armed aerial cruiser for the aerial defenses of New York, with a trained pilot, and the fully equipped aerial coast patrol station at Port Washington, L. I., which appears elsewhere in this number.

August Belmont presented to the club a Paul Schmidt hydroaeroplane equipped with an American motor, to be used for training purposes, a duplicate of which has been presented to the Navy Department.

Air Ministry Urged

The establishing of a Department of Aeronautics, with a Minister of the Air, was urged by Rear Admiral Peary, Congressman Murray Hulbert and Congressman Caldwell and the proposal received enthusiastic applause.

RODMAN WANAMAKER OFFERS LARGE AIR CRUISER FOR AERIAL DEFENSE OF NEW YORK—PROPOSES DEPARTMENT OF AERONAUTICS AND AIR MINISTER

RODMAN WANAMAKER has once more shown his public spiritedness and practical patriotism. He has presented to the Government through the Aero Club of America, the use of a 400 h.p. Curtiss air cruiser, completely equipped, and the well appointed coast patrol station at Port Washington, Long Island, for the protection of New York.

Mr. Wanamaker's letter making the offer, which was read at the Aero Club of America banquet, reads as follows:

New York, March 30, 1917.

Alan R. Hawley, Esq.,
President, Aero Club of America,
297 Madison Avenue, New York City.

My dear Mr. Hawley:

Six months before the terrible war broke loose in Europe, you will remember I wrote you under date of February 4, 1914, a letter of which the following are some excerpts:

"In the cause of science and in the interest of world peace, I have the honor to announce first of all to the Aero Club of America, my intention to make a purely scientific test of aeronautic power by crossing the Atlantic Ocean by one flight if possible.

"I have said this undertaking is in the interest of world peace. Let me explain what I mean. Once across the ocean in one flight of an aircraft and the nations of the earth will awaken to a realization of the tremendous importance aeronautics may prove to be to every nation.

"This year we are celebrating a hundred years peace between Great Britain and the United States, and it would be a fitting climax to this celebration, if those two countries could link themselves more closely together by this international flight across the ocean, demonstrating to the world that the time for disarmament of nations is at hand, if for no other reason than that because aeronautics has reached a stage where even the greatest dreadnaught battleships may become futile in their power.

"The crossing of the Atlantic by air is not a matter merely of initiative, nor of daring, nor even of skill; it is a problem of science."

The above extracts, written in 1914, will again recall to your attention the importance of the fact that immediate, intelligent and efficient action should be taken in the formation of aeronautic stations throughout the length of our coast, to be equipped with proper guns, and with men trained for coast defence. This important action can best be accomplished by the patriotism of our citizens, who, realizing the importance of the work, should immediately build such stations, ready to be used by the Government for coast defence.

In August, 1914, I was in London, awaiting news that the "America" had been thoroughly tested, and hoped to greet Commander Porte on his arrival in Great Britain. When it became apparent that there was to be war, he immediately returned to his country. In the interim, have been busily engaged in perfecting still larger machines and studying scientific methods of importance to such an extent that at the present moment, undoubtedly there are under construction the best machines in the world, which will be ready to take their part.

During the past year I have established aviation training stations at Port Washington, L. I., and Palm Beach, Fla., and have already donated the use of the Palm Beach station for the training of men for Government aeronautic service. I now wish to add to the equipment of my Port Washington Station one air cruiser of the "America" design, fitted with two 200 horsepower motors, a suitable aeroplane gun and a well trained pilot and a capable mechanic (both already in my employ) and to offer through you to the Government, for as long a time as they desire, the air cruiser, the pilot and mechanic. The Government will undoubtedly want to furnish the gunner, etc. This will give the Government the first Coast Patrol Station in America equipped with an armed air cruiser capable of hunting submarines, locating mines and convoying troopships, and will give New York City its first real aerial protection.

In March, 1916, a special messenger was sent to Washington, to both the army and navy departments, with all blue prints and details of information in my possession relating to work that was still in progress, so they would be fully informed, and since that time still further progress has been made.

All of the information now in possession of the Government, from whatever source derived, covering this vast field of vital importance, should be gathered together under the direction of a most capable man, a Cabinet officer of the United States, the Secretary of Aeronautics, and who, understanding business methods, can formulate and organize a substantial air service without the loss of unnecessary time at this intense moment. Very sincerely yours,

(Signed) Rodman Wanamaker.

Photographs and the description of the Curtiss air cruiser were printed in the last number of AERIAL AGE.

AERO CLUB ENTHUSIASTIC OVER PRESIDENT'S MESSAGE

THE President's message was received with great enthusiasm at the Aero Club of America. The Board of Governors held a special conference on the evening of the message and decided to promptly take steps to mobilize the civilian aerial resources, preparing same for the Army and Navy to take up. The club has received close to 3,000 applications from men who would like to learn to fly, about two hundred of which are men who are willing to pay for their own training and purchase their own aeroplanes, so as to be available to meet an emergency. As neither the Army nor Navy have facilities to train more men, the club has been developing plans to establish a chain of aviation training schools and is ready to carry the plan into effect as soon as it receives word from the Army and Navy.

Messrs. Alan R. Hawley, Rear Admiral Bradley A. Fiske, Rear Admiral Robert E. Peary, Henry Woodhouse, John Hays Hammond, Jr., Eugene S. Willard and Dr. Schuyler Skaats Wheeler have been occupied in the past week formulating plans for the aerial defences of the Third Naval District, having been asked to do so by Rear Admiral Nathaniel R. Usher, the Commandant of the Third Naval District.

THE NEWS OF THE WEEK

Princeton Gets Two Aeroplanes

Princeton, N. J., March 31.—That Princeton will have aircraft hovering above it in a not far distant time is not a rash conjecture. Two flying machines already have been given to the Aviation Corps of the university by a graduate and are expected to arrive in the university town within a few weeks' time. Moreover, several more machines have been promised to the undergraduates by the alumni body.

Dr. Joseph Raycroft, of the university faculty, is organizing the corps. He has already selected a field in Princeton for the work and is securing several instructors and mechanics to assist the students in their training. It is probable that the aviation schools will be conducted through the summer months. Several Princeton men, including Hobey Baker, football and hockey player, and June Salmon, baseball player, are already in the aviation service of the Government. Since the break with Germany several undergraduates of the university have joined government aviation schools.

Yale Aviators Training

The twenty-eight Yale students, who left recently for training in aviation at Palm Beach, have been thoroughly schooled before being assigned for flying. They have been studying the art of aviation as part of their regular work at the university, and recently employed the services of O. B. Whitaker of the Sperry Gyroscope Company, as their instructor in aerial navigation.

The instruction in aviation was begun after a group of Yale students, capable of providing aircraft, consulted with the university authorities. The latter readily gave their approval of the plan and arrangements were made for the work to count as part of the required schedule, even though aviation is not a required subject for a degree from "Old Eli."

Prominent among the students who started the Yale flying class is Trubee Davison, son of H. P. Davison, a member of the firm of J. P. Morgan and Company. The younger Mr. Davison has been actively interested in flying for some time and he soon worked up enthusiasm among his college mates, including A. Lovett and others from families equally prominent in American business.

After organizing themselves into a class, these Yale aviators engaged Mr. Whitaker to become instructor in the art of navigating the air. The course, which was mapped out for the students under his supervision, included thorough training in that art, particularly the use of the most up-to-date aerial navigating instruments, such as automatic pilot, synchronized drift set, and Creagh-Osborne compass. With this apparatus Mr. Whitaker has been able to give demonstrations at the same time he describes their uses.

Benoist School Open for Season

Sandusky.—If all signs do not fail that part of Lake Erie around Sandusky Bay will probably see more hydro-aeroplane activity than any other part of the great lakes. The Benoist Aeroplane Company, located at Sandusky, Ohio, are preparing to open their Summer School on April 5th with more than a dozen students and about three flying boats, besides that, arrangements are being made for a regular scheduled passenger line making ten trips a day between Sandusky and Cedar Point and another passenger line making a round trip in the morning and a round trip in the afternoon to Put-in-Bay, also a line between Sandusky and Detroit. For the Detroit run they expect to put in a twin motored seven-passenger machine and will make two or more round trips a week.

Army and Navy News

First Lieut. Arthur J. Coyle, Aviation Section, S.O.R.C., to active duty at Signal Corps Aviation School, Mineola, Long Island, N. Y. (March 24, War D.)

First Lieut. Birdeye B. Lewis, Aviation Section, S.O.R.C., to active duty at Fort Sam Houston, with 3d Aero Squadron. (March 23, War D.)

The 6th Aero Squadron, Signal Corps, will proceed to Fort Kamehameha for station. (March 12, H.D.)

Sergt. 1st Class Ernest E. Hagelin, Aviation No. B, Signal Corps, Aviation School, Mineola, Long Island, N. Y., is transferred to the C.A.C. 5th Co., Fort Totten, N. Y., as private for duty. (March 19, E.D.)

The following sergeants of the Signal Enlisted Reserve Corps from active duty in Aviation Section at the Curtiss Aviation School, Newport News, Va., March 25, 1917, to their homes: Sergts. Walter V. Barneby, Edward R. Kenneson, William T. Rolph and Howard P. Culver. (March 22, War D.)

S. A. E. to Change Name April 19

New York.—In order to further standardization work in connection with Government preparedness work, the Society of Automobile Engineers will change its name April 19 to Society of Automotive Engineers. At that time the engineers who were formerly members of the American Society of Aeronautic Engineers, the Society of Tractor Engineers and engineers connected with the company members of the National Assn. of Engine and Boat Manufacturers will be working together with those who have been members of the Society of Automobile Engineers, always with the welfare of the nation at this time held constantly in view. The culminating decision to change the name was based on government cooperation in time of stress.

The Preparedness Committee of the S. A. E., consisting of President G. W. Dunham, past President W. H. Vandervoort and Vice-President J. G. Vincent, is not only making a classification of the society members with reference to qualification to cooperate with the government and keeping in close touch with various Government officials, but is taking an active part in the big plan under way to increase the membership, drawing upon engineers in the various automobile fields.

Duesenberg Motors Refinanced

New York.—The Duesenberg Motors Corp., has succeeded the Duesenberg Motor Co., St. Paul, and the Loew-Victor Engine Co., Chicago, its capital being $1,500,000, of which $1,050,000 is paid in. The company has located a plant in the East at Edgewater, N. J. The engineering and experimental forces have already been moved from Chicago and the company will, in a short time, be building on a commercial basis a line of Duesenberg motors for both automobiles and aeronautical purposes, devoting the output of the Chicago plant to marine models. The Loew-Victor Engine Co. has been building one of the largest high-speed marine motors on the market for the past year. These motors were designed by F. S. Duesenberg. The Chicago plant will in the near future be consolidated with the Edgewater plant.

The personnel of the organization is as follows: Directors, J. R. Harbeck, F. S. Wheeler, Charles Stollberg, K. S. Breckenridge, L. A. Welles and F. B. Page. The first five are all of one of America's largest industrial corporations. Mr. Page is vice-president and general manager of the E. W. Bliss Corporation.

J. R. Harbeck, who has been president of the Loew-Victor Engine Co. since its formation, is president and managing director of the Duesenberg Corporation. E. L. Decker is assistant to the president; H. A. Wing is secretary and treasurer; C. B. Page is general manager in charge of production, and N. G. Rose is general sales manager. F. S. Duesenberg is chief engineer. A. S. Duesenberg is assistant engineer. M. M. Whitaker is assistant engineer and naval architect. G. A. Beilstein is purchasing agent and F. E. Lampe is superintendent.

Personal Paragraphs

M. H. Needham has resigned as general manager and treasurer of the Bailey Non-stall Differential Corporation. He has become associated with the Barrett-Cravens Company, manufacturers of the Barrett Multi-truck, time clocks and other factory equipment.

Army Fliers Hunt U-Boat Off Long Island

New York.—For the first time in the history of American military aeronautics American aeroplanes flew last week over our coast line to guard against the attack of enemy submarines. Theory was omitted. German U-boats were believed to be off Montauk Point. Four fliers from the government school at Mineola—Instructors Leonard Bonney, B. B Acosta, A. S. Allen and A. W. Briggs—were detailed to spend three days away from their base in looking for them.

It was not work stimulating the conditions of war. It was under a reproduction of the conditions of warfare.

Last Tuesday morning these four fliers rose from the Mineola field in a forty-mile an hour gale and a bad fog. They were detailed to patrol the Long Island coast from Oyster Bay to Montauk Point, while Governor's Island aviators watched over the shore from the island to Oyster Bay. Two of the men, Acosta and Briggs, were out for three days. They did

The Navy Aeronautic Station at Pensacola, Florida not return to their headquarters, merely landing when they were forced to. A new supply of gasoline was obtained at the dealer's nearest to the place of landing. During the night the 'planes were left in the field in which they had landed, while the pilots slept in the nearest inn.

The fliers were detailed to watch for submarines—an experinment which the officers at Mineola have been intending to make for some time. The belief that undersea craft had been sighted near Montauk Point made the patrol work more than an experiment.

Torpedo boats and smaller craft were easily sighted by the aviators. They saw no submarines, but declared that the sandy bottom in that part of the Sound would have made the detection of U-boats a simple matter.

On his second day out Bonney's engine went dead when he was flying near Melville. He was forced to land as best he could. He came down in the limbs of a tree. The pilot was unhurt, but the aeroplane had to be taken to pieces in order to get it back to the field.

Allen's supply of gasoline gave out on his first day, when he was flying over the water near Crane Neck Point. The stiffness of the breeze prevented his gliding for a long distance, and his craft landed in shallow water near the shore.

The Goodrich "Blimp"

By permission of the Secretary of the Navy the following description of the Blimp dirigible balloons, which the B. F. Goodrich Company is building as rapidly as possible for the Government so that they may be available for war scout work, is made public:

"The shape of the envelope of the Blimp dirigible somewhat resembles that of a cigar. The entire length, from tip to tip, will be 160 feet and the maximum diameter 31.5 feet, but the maximum width over the tail fins will be 36.2 feet. This huge envelope will displace 77,000 cubic feet.

"Suspended from the envelope will be a rigidly built car, spacious enough to carry a pilot, an observer, the necessary accessories for determining altitude, speed, etc., and a 100-horsepower gasoline motor of the latest improved type. Provision is also made for carrying ballast, which, when thrown out, will enable the dirigible to reach an altitude of 7,500 feet with safety.

Wardrop Addresses Cleveland S. A. E.

Cleveland: At the March meeting of the Cleveland Section of the S. A. E., G. Douglas Wardrop, Editor of AERIAL AGE, gave a talk on "Aircraft in the Great War," illustrated by stereopticons and motion pictures, and showing the evolution of the application of aircraft in war service. The engineers were enthusiastic concerning the presentation, and considerable feeling towards the organization of an Aero Club in Cleveland was generated.

Mr. Wardrop also addressed the Engineering Society of Cleveland at luncheon, and there also great interest was evinced in the subject.

Aeronautic Division S. A. E. Meets

Buffalo: An important session of members of the Aeronautic Division was held in Buffalo on the 16th, Chairman Manly, Captain V. E. Clark, C. B. King, J. G. Vincent and Coker F. Clarkson being present.

With reference to the question of the system of measurement to be used basically in expressing dimensions of aeronautic standards, it was the sense of those present that it will be necessary to continue the use of the inch system in connection with hex stock sizes, bolt and screw sizes and threads (except spark-plug shell thread), gear cutters, gear centers and reamer sizes. The matter of spark-plug standardization for aeronautic engines was taken up again, the previous recommendation of the Division having been referred back by the Council owing to apparent discrepancies. It is felt that in addition to specifying the 18-mm. diameter 1.5-mm. pitch thread for the spark-plug shell, the length of this threaded portion should be specified as 16 mm. A specially appointed committee of the Division will report on the question of tolerances for diameters. It is expected that all of the other aeronautic spark-plug dimensions will be expressed in inches.

Taking up the question of propeller-hub capacity, the opinion was expressed that this should be based on torque and not on horsepower. Messrs. Vincent, Caldwell and Manly will submit a report on specification of propeller-hubs of various capacities, propeller-hub locking fittings and on stresses in propellers.

The following dimensions (in inches) for engine supports were recommended:

Distance between timbers........	12	14	16
Width of bed timbers............	2	2¼	2½
Distance bet. centers of bolts	14	16¼	18½

(anchor bolts to be ½ in. diameter)

According to the last action of the Division, the direction of engine rotation should be designated according to the following statement:

"The direction of engine rotation is normal when the final power delivery member of the engine rotates anti-clockwise, viewed facing the power-delivery end. Opposite rotation is anti-normal."

The terms suggested would not be in accord with the latest recommendation of the National Advisory Committee for Aeronautics and no final action will be taken until the views of the two bodies can be harmonized. One important consideration is that on multiple-engined machines having two or more propellers, the engines are frequently described as "right-hand" and "left-hand," depending on position in the machine; while at the same time the engines are likely to be made to rotate in either direction regardless of position, because air-blast may be needed over or under the stabilizer. The great advantage of the terms recommended by the Division ("normal" and "anti-normal") to indicate engine rotation, is that whereas they are well known descriptive terms, they have never been used in connection with engine rotation, and there is therefore no possibility of conflict with past practice in the aeronautic or allied industries. In the case of dual-engined machines there has been considerable confusion from misunderstood use of "right-hand" and "left-hand," as to whether position on machine or rotation of crankshaft was meant. The use of the terms recommended by the Division will conflict in no way with the designation of right- and left-hand propellers as heretofore in past practice.

Following the action of the Marine Standards Division, the Aeronautic Division has checked over in part the list of S. A. E. standards established for automobile practice, as to suitability in aeronautic practice. The S. A. E. standard screws and bolts are applicable for the general run of work, but there should be supplemental standardization of heads and nuts for use where lightness is requisite and to minimize air resistances. C. B. King, F. G. Diffin, and E. H. Ehrman have been appointed a special committee on this subject.

The S. A. E. steel specifications are considered applicable, but an additional screw stock specification is suggested.

In addition, the following S. A. E. standards are considered applicable in aeronautic practice:

Heat treatments, test-specimens, ball-bearing sizes, Throttle levers, carbureter flanges, magneto dimensions, cotter-pin sizes.

The aeronautic engineers wish to check up carefully the S. A. E. standard of piston ring groove dimensions.

It is felt that the S. A. E. flared tube unions cannot be considered applicable now in a final way and there is a difference of opinion as to the type of gasoline lead which will prove most effective at an early date in aeronautic engine practice.

The opinion has been expressed that the S. A. E. ells and tees are too heavy for use on aeroplane engines.

A flange for use in mounting twin carbureters has never been standardized by the Society. This question will, however, be taken up by the Aeronautic Division.

The Division expects to take up definite consideration of the following subjects at an early date, its next regular meeting being scheduled for April 20: turnbuckles, wire ends and eyes, shackles and rod end pins, clip ends, fabric test specifications, dope and varnish specifications, handpumps and drain-plugs for pontoons, high-grade thin-wall tubing, tachometer connections, wing attachments, controls, screw test specifications, safety belt, marking gas and oil lines, performance test, hand air-pumps and water connections. Special committees have been appointed on practically all of these subjects.

Foreign Pilots Get Licenses

Redwood City, Cal.—Graduation exercises for the Christoffersen Aviation School were held recently under the direction of Guy H. Slaughter, representing the Aero Club of America. Pilot licenses were granted James Martin of Vancouver, B. C., and Arthur Gulbera of Guatemala.

Mrs. George French Shelton, of Butte, has enrolled as a student of the Christoffersen Aviation School. She says it will be at least ten weeks before she can motor back to Butte, and she will put in the time learning to fly.

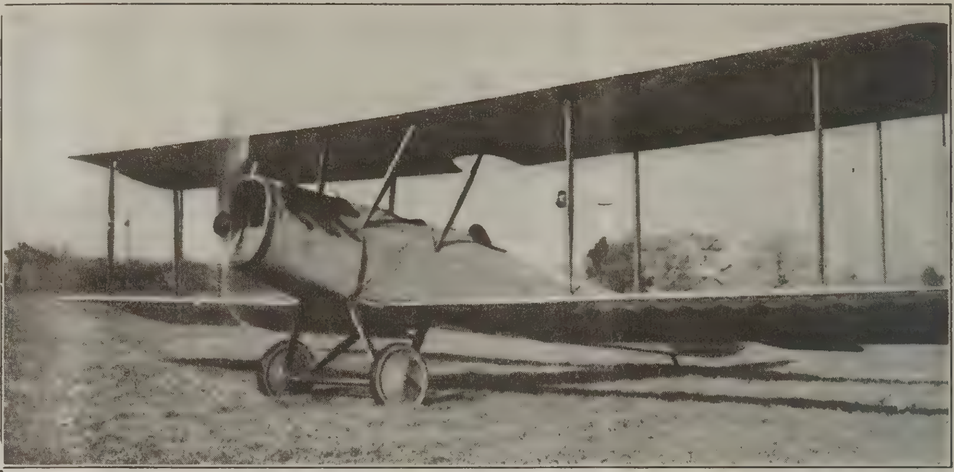
College Athletes to Enlist

Philadelphia.—James E. (Ted) Meredith, famous former Pennsylvania athlete and holder of the world's quarter and half mile running records, has announced that he intends to enlist in the aviation corps, and is arranging his business affairs so that he can start taking instructions as soon as he is accepted.

Donald Lippincott, former Pennsylvania track star, along with several other Pennsylvania athletes, has also signified his intention of joining with Meredith.

The Congressmen who recently visited the Army Aviation School at San Diego, Cal. Left to right: Admiral Coperton, Commander of the Pacific Fleet; Congressmen C. H. Dillon, H. Z. Osborne, T. L. Ruby, E. W. Roberts, T. F. Butler, L. P. Padgett, William Kettner, and Colonel William Glassford.

WRIGHT-MARTIN MODEL V TRACTOR



THE splendid Wright-Martin, 150 H.P. Reconnaissance Tractor is the first Hispano motored aeroplane to be designed and flown in America. It is a recent effort of Mr. Chance M. Vought, whose versatility as an aeronautic engineering director and designer is shown by a long list of remarkable aircraft successes, including the famous Mayo biplanes.

This Wright-Martin 2-seater was exhibited at the 1916 Aero Show, where it excited universal favorable comment because of its fine design, simplicity and modern production possibilities.

Rapidity of production has not always been considered in machines which have been designed to be efficient dynamically. In the Model V, the ease with which fittings could be manufactured was given the same attention as the design of the machine as a whole. Fittings are substantial throughout, and in most cases are steel stampings, embossed and die formed from special steel, heat treated.

In the issue of AERIAL AGE of February 5th, a complete description of the Model V was given, together with detailed specifications and photographic illustrations. A general summary of the description is given below to enable a better understanding of the characteristics of design shown in the accompanying outline drawing.

General Dimensions

Span, upper and lower planes	39′-8½″
Chord	5′-9½″
Gap	5′-7″
Length over-all	27′-2″
Height over-all	9′-5½″
Weight, complete, without fuel	1725 lbs.
Useful load (pilot, observer, supplies)	595 lbs.
Weight of fuel for 6 hours' flight	460 lbs.
Motor, Simplex Model A Hispano-Suiza	150 H.P.

Planes

The planes are staggered, the upper being 12″ in advance of the lower. Dihedral angle, 1 degree 45 minutes. There is no sweepback. Upper plane composed of three sections and lower plane of one section butting into either side of the fuselage.

Ribs are built up with spruce battens and poplar webs, glued and nailed together and reinforced to prevent longitudinal shear. Leading edges of plane are of spruce; trailing edges of white ash. Main spars of I section spruce.

Area of upper plane, exclusive of ailerons, 223.2 sq. ft. Lower plane, exclusive of ailerons, 206.8 sq. ft. Area of the four ailerons, 64.6 sq. ft. Total area of supporting surface, exclusive of ailerons, 430 sq. ft. Loading per sq. ft., 5.86 lbs. Loading per b.h.p., 16.86 lbs.

Body

Rearward of the planes the fuselage tapers to a vertical knife edge, which serves as an anchorage for the fin and rudder. With the exception of the steel motor mounting, the construction is of ash and spruce logerons and cross members braced with Roebling's vanadium steel wire. In the forward part of the fuselage a substantial system of "follow-through" has been employed.

Covering near the motor and the curved top as far as the pilot's seat, is aluminum. Covering elsewhere of linen fabric. Quick access to the interior truss work of the body is permitted by the removal of a detachable deck.

The rear cockpit is provided with Dep control. On the dashboard are an altimeter, slip indicator, air speed meter, clock, oil and air pressure gauges, tachometer, thermometer, primer, shut-off valve, hand air pump and ignition switches.

Landing Chassis

The chassis is composed of two sets of ash V struts of streamline section combined with a streamlined system of twin-parallel steel spreader tubes. The struts are attached to the body with steel clip and pin fittings.

Axle is nickle-steel tubing specially heat treated. Wheels 26 by 4 inch. Tread of wheels, 5′-4″. Weight of the chassis complete, 86 lbs.

Tail Group

The horizontal stabilizer is double cambered, with rib structure constructed over an I section spruce spar located 14 inches back of the leading edge. External bracing to the forward part of the horizontal stabilizer has been eliminated by the use of this substantial spruce spar, besides providing for the necessary depth for the double cambered profile. Interbracing is secured by streamlined tubing outside stays so located and calculated as to take all the emoennage drift, control thrust and vertical loads.

Elevator and rudder ribs are sparred and the surfaces provided with a light spruce spar disposed 10 inches forward of the trailing edge to aid in equalizing the load on the ribs.

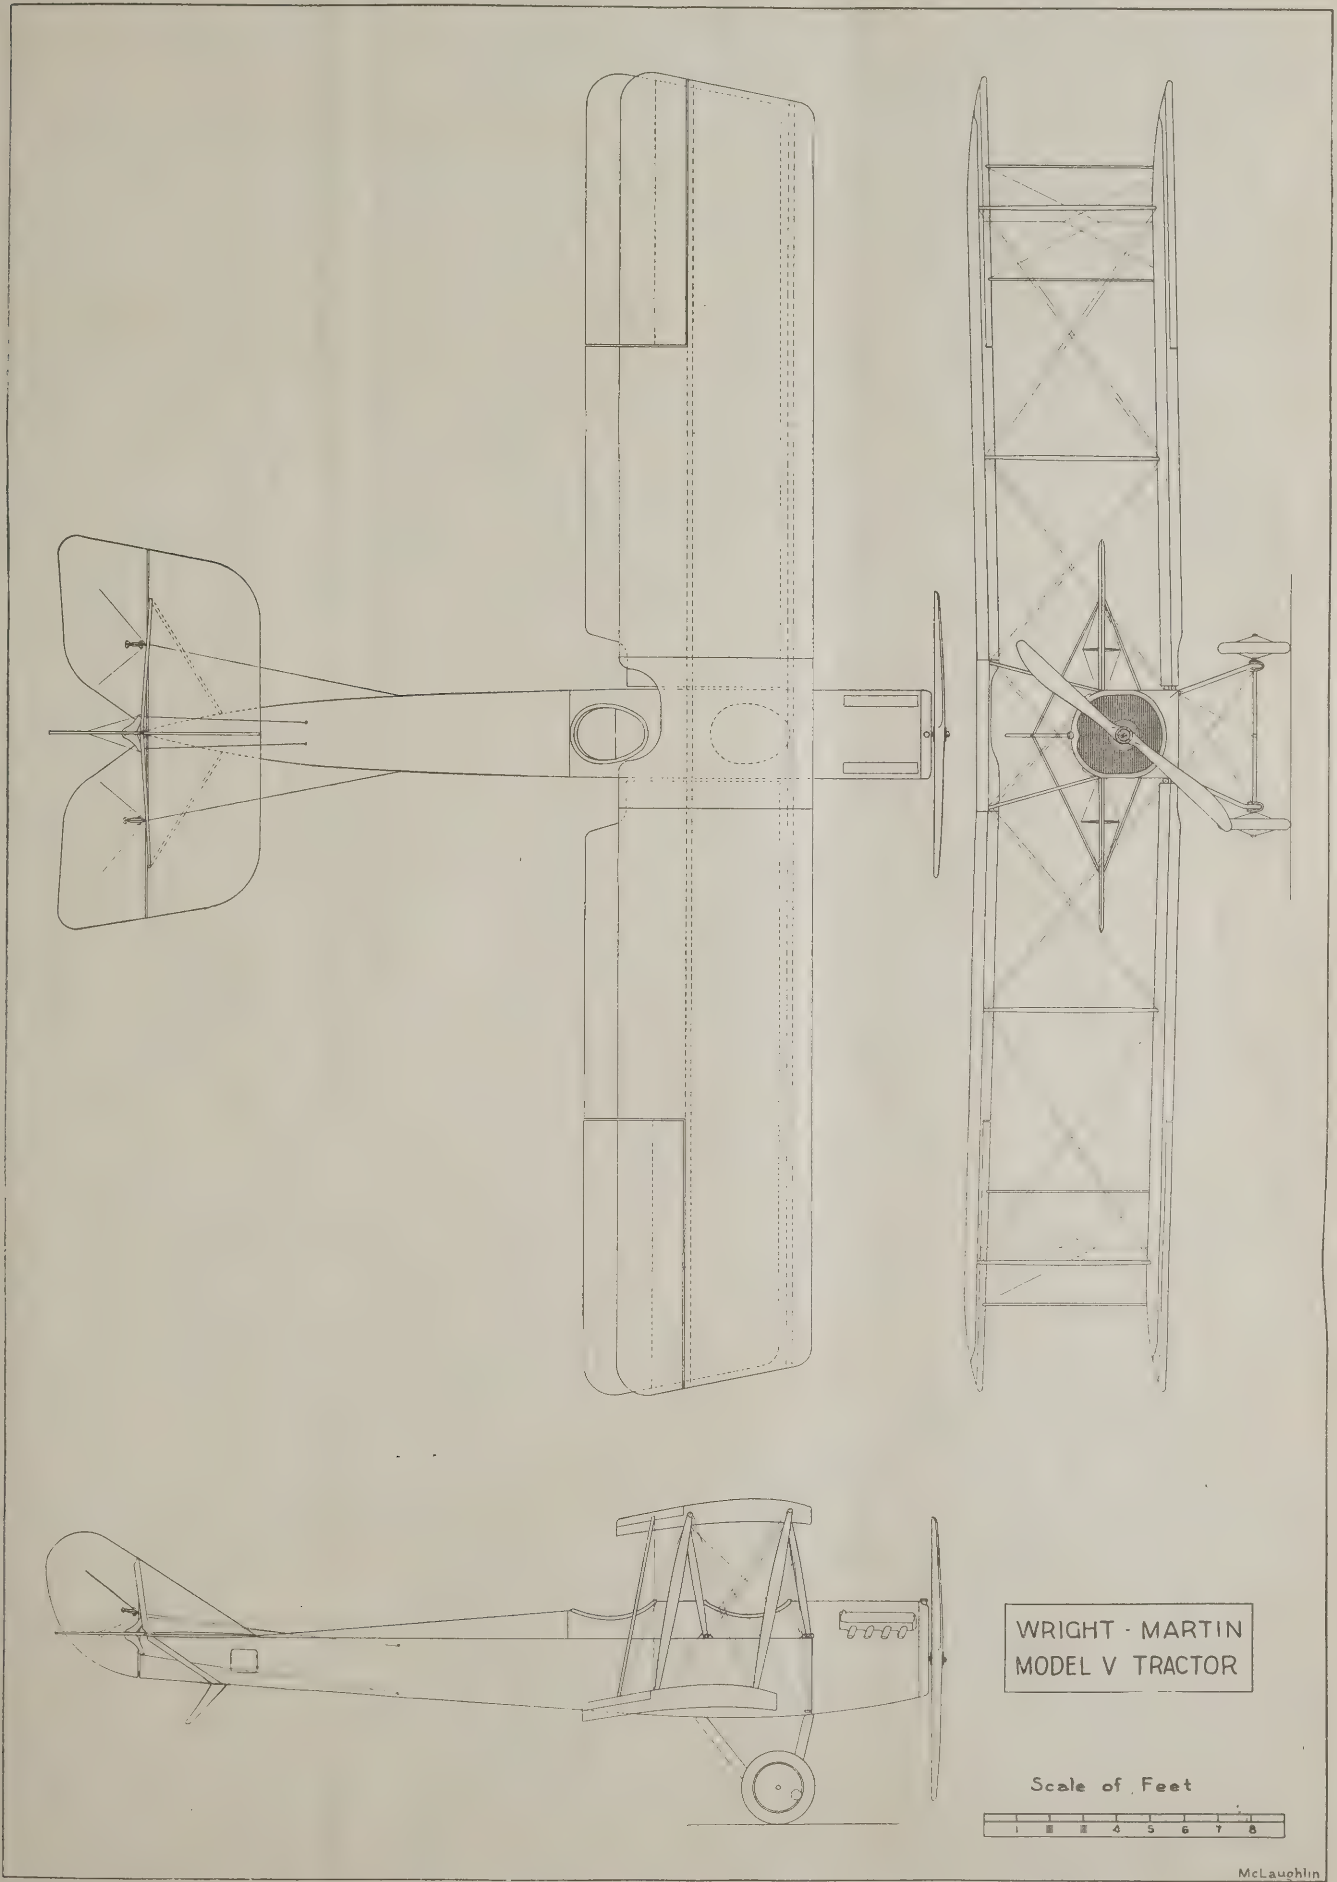
No welding operations are employed in making the frames, and all ribs and spars are attached to tubular frame members by sheet steel socketing clips brazed in place.

Motor Group

An article dealing with the Hispano-Suiza 150 H.P. motor, appears in this issue of AERIAL AGE. Its rated H.P. is developed at 1400 r.p,m. An oak propeller 8′-4″ in diameter and with a 5′-7½″ pitch rotates in a counter-clockwise direction.

Main fuel tanks are placed longitudinally and to the rear of the front seat in padded floor cradles. Fuel supplied by pressure to the service tank located in the cowl aft of the front cockpit.

The Wright-Martin Model V, piloted by H. S. Rinehart



WRIGHT - MARTIN
MODEL V TRACTOR

McLaughlin

THE CASE FOR THE LARGE AEROPLANE

By F. HANDLEY PAGE, A.F.Ae.S.*

(*Continued from page* 86)

Attention is drawn to the fact that the loading expressed in weight per unit of area, and the value of the density of the air expressed as weight per cubic unit of air, appear in the same form in both velocity and h.p. multiplying factors. It follows, therefore that these curves are correct for any loading or height above ground level, the comparison between the two being correct as long as the loading is equal in both cases. The only alteration is the multiplying factor of the horizontal and the vertical scales.

It is hardly correct, however, to compare two machines, one of which has a slower landing speed than the other. For correct comparison the slow landing speed of a machine fitted with planes to R.A.F.3 section should be increased so that it is the same as that for R.A.F.6. The area of the R.A.F.3 planes should be decreased, thus increasing the loading until the two slow speeds are identical. The loading is increased in the ratio of 1 to 1.05. To compare the resulting curves it is better to keep the multiplying factors of the vertical and horizontal scales the same and alter the R.A.F.3 curve. Since the loading enters into the multiplying factor of the h.p. and velocity scales equally each value of the R.A.F.3 curve must be increased 1.05, both as regards h.p. and velocity. A new curve is now obtained for R.A.F.3 having the same slow speed as R.A.F.6 and the multiplying factors being the same for both. These new curves will again be true for all heights.

We will take an actual practical example. Assume a machine weighing 2,200 lbs. with a loading of 5.9 lbs. per sq. ft., and that at the ground $p/g = 425$. Then from equation (4) $a = 50$ and from (5) $b = 200$. For R.A.F.3 the value of Ky (maximum) is .675, and of $1/\sqrt{Ky}$ is 1.215. For R.A.F.6 the value of Ky (maximum) is .605 and of $1/\sqrt{Ky}$ is 1.285. The slow landing speed of R.A.F.6 for the loading of 5.9 lbs. per sq. ft. is $50 \times 1.285 = 64$ ft. per second or 43.5 miles per hour. The slow landing speed of R.A.F.3 for the loading of 5.9 lbs. per sq. ft. is $50 \times 1.215 = 60.5$ feet per second or 41.2 miles per hour.

The new curve for R.A.F.3 will be for a slow landing speed of 43.5 m.p.h., and the loading will now be $\frac{43.5}{41.2} \times 5.9 = 6.25$ lbs. per sq. ft. Each point on the old R.A.F.3 curve must have its vertical and horizontal value increased in this proportion—*i.e.*, multiplied by 1.05. The new R.A.F.3 curve was plotted in this way.

The minimum height of either of these curves above the horizontal is the minimum h.p. required by the planes, and, neglecting body resistance, the curve with the minimum value will have the highest climbing speed. It must always be borne in mind that the curve with the higher loading will have the smaller planes, and therefore weigh less. Allowance must be made for this in effecting the comparison.

The three curves can now be compared. For the same loading and h.p. available R.A.F.3 has the slower landing speed, the higher climbing rate, but the slower top speed. If the loading be increased R.A.F.3 loses its advantage in climbing rate, and does not attain the same high speed as R.A.F.6. In a similar manner any other or more modern planes may be compared.

It is interesting to note, in passing, that at 10,000 ft. height where $p = .055$ the value of a will be increased to 59 and of b to 236. The effect of height is to reduce the h.p. required for any given speed, and also the speed range by increasing the slow speed. Owing to the h.p. scale being increased, the minimum h.p. required for flight is increased, and, therefore, quite apart from reduced engine h.p., the excess h.p. available for climbing is reduced.

The general range of velocities for a high speed machine is from 50 to 130 m.p.h. or 73.5 to 190 ft. per sec. In general the value of $1/\sqrt{Ky}$ will lie between 1.4 and 3.8. For a slow speed machine flying from 40 to 90 m.p.h. or 59 to 132 ft. per sec. $1/\sqrt{Ky}$ will vary between 1.1 and 2.7. Any comparison between plane curves must be made between the velocity limits of the type of machine considered.

So far the comparison has only been extended to the planes of a machine. The body resistance remains to be dealt with.

The equation may be written:—

$$\text{Resistance} = Rb \cdot \frac{p}{g} \cdot V^2 \quad . \quad . \quad . \quad (11)$$

$$\text{H.P. required} = Rb \cdot \frac{p}{g} \cdot \frac{V^2}{550} \quad . \quad . \quad (12)$$

This equation is identical in form with the plane h.p. curve. The term Rb is the product of the values of a resistance co-efficient Kxb and a body area S. The equation may therefore be written:—

$$\text{H.P. required} = Kxb \cdot \frac{p}{g} \cdot \frac{S}{550} V^2 \quad . \quad (13)$$

Whence inserting the value of V in equation (2) above

$$\text{H.P. required} = \frac{Ky}{Kxb}\sqrt{\frac{1}{Ky}} \cdot \frac{S}{A} \cdot \frac{W}{550}\sqrt{\frac{W}{A} \cdot \frac{g}{p}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

The H.P. required for body resistance can be plotted to the same scale as those for the planes. The values would be divided by

$$\frac{W}{550}\sqrt{\frac{W}{A} \cdot \frac{g}{p}} .$$

There would then be plotted for the body resistance H.P. the value of:

$$\frac{Ky}{Kxb}\sqrt{\frac{1}{Ky} \cdot \frac{S}{A}} \quad . \quad . \quad . \quad (15)$$

The h.p. required for body resistance can now be added to the plane h.p. curves. Let us assume that the machine referred to in paragraph 10 above requires 10 h.p. to overcome body resistance at 100 ft. per sec. Below the horizontal line has been added a curve of h.p. required to overcome body resistance, the scale of h.p. being the same as that for the planes. The total height between the two curves for any value of $1/\sqrt{Ky}$ gives the total h.p. required at that speed. It is interesting to note that these curves are correctly placed in respect of one another for all heights. This method of plotting and the curves so obtained give the necessary basis for a comparison between different machines, and reference will be made to them again later in the paper, after discussing the structural side of the question.

Twin-motor hydroaeroplane constructed by the U. S. Navy

The Effect of an Increase in Size on the Structural Weight of Aeroplanes

Attention has already been drawn to the fact that an improvement in the aerodynamical qualities of the machine as the size increases may be partially or completely nullified if the increase in size is accompanied by a disproportionate increase in weight. I will, therefore, accordingly examine the rate at which the weight increases with increase in size.

In this discussion we shall leave out the weight of the power unit comprising engine, tanks, and fuel, as well as the useful load, whether consisting of men or dead weight, such as guns, bombs, etc. We will confine our argument to the weight of the machine structure, that is, the portion which supports the load whether on the ground or in the air, with the necessary directing surfaces and their attachment to the main portion of the aeroplane. In the latter category come the planes, the fuselage, and the chassis, and these will be considered seriatim.

In all discussions on weight saving there is the general question as to the best utilisation of materials with the varying size of machines. As the machine is made smaller, so eventually a limit is reached beyond which it is not possible to decrease the minimum thickness of the material and retain adequate local strength. Especially is this the case in aeroplane work, where the members are usually stressed as struts, and for which, therefore, a hollow tubular construction is the most efficient form from the point of view of minimum strength for a given weight. In making tubular members, whether these be plane spars, fuselage, struts, or longerons, it is not advisable to decrease the thickness of the walls below 5-16 in. to 1-4 in. Even this is on the small side when allowance is made for errors in workmanship, and the fitting in of the necessary tongue piece to make a secure joint. Considerable economies can be effected in weight-saving with increase in size in this manner.

Local strength, too, determines the construction of subsidiary parts of the machine, such as the tail skid, the ribs, tail planes, a local strength that does not need to be increased with increase in size of the machine, and here, again, weight economy can be effected.

This better utilisation of material more than offsets the increase in weight that would occur in the planes provided that they were increased in a geometrically similar manner and the loading aspect ratio and section kept the same. In a machine of which I can show you the photos later the plane weight per square foot is less than a small one for the same factor of safety, and the total plane weight is a lesser percentage of the gross weight.

The fuselage weight, owing to the better utilisation of material, is considerably decreased The chassis weight remains about the same.

The Effect of an Increase in Size Upon an Aeroplane's Performance.

A general comparison can now be effected between aeroplanes of different sizes on the basis of the curves described in Section II., the total weight of the aeroplanes considered being modified according to the size in accordance with the conclusions of Section III. An examination of equation No. 9 in which H.P. equals $b \times Kx/Ky \times \sqrt{1/Ky}$ shows that, provided that similar planes are used and that the weight per H.P. remains the same, the same plane curve represents all machines. These curves as plotted are, in fact, curves of H.P. required per pound weight of the machine for a given loading per square foot. Let us now examine the lower curve of H.P. required for body resistance and refer to equation 14. Provided that the area of the body increases in the same ratio as the plane area, this lower curve will still, for any size of machine, be correct in relation to the plane curve ploted above, and the summation of the two ordinates or the distance between the two curves will represent the total H.P. required, the scale being increased in proportion to the increase in ratio. The greatest resistance of an aeroplane is that of the body. This, for smaller shaped bodies, would increase as the square of its lineal dimensions, whereas its volume would increase as the cube. It follows, therefore, that the resistance of the fuselage per unit of volume will decrease with the increase in size of the aeroplane. The lower curve will have to be modified to meet these changed conditions. This decrease in weight will have the usual cumulative effect of decreasing the weight of all the rest of the machine.

The curves which are plotted are for H.P. per unit weight of the whole machine, and do not show so graphically the superiority of the large machine as if the curves of H.P. per unit of useful weight had been plotted instead of gross weight. In this case the curves for planes and body would have their vertical ordinance increased with the proportion of useful to total weight. The balance in favour of the large machine is thus apparent directly we compare machines of approximately the same total weight per H.P.

---

* *Lecture.*

The conclusion that may be drawn from the above theoretical considerations of the aerodynamical and structural qualities of the large machine are that for the same total weight carried per H. P. the big machine will effect the better performance.

THE LARGE MACHINE FROM THE PILOT'S STANDPOINT.

There has been very much less experience in the flying of large machines than with small ones, and, therefore, pilots are not so accustomed to their use, neither is the experience wide enough to draw general conclusions. It may, however, be safely said that large machines can be built to operate quite as easily and fly with as little fatigue as the best of the small ones. No Servo-motors are required for the controls provided the controlling surfaces are properly balanced. There is less work in flying a large machine owing to the wind gusts, which seem large to a small machine, being relatively small in their effect on a large one. A large machine will plough its way through gusts without any control being necessary, whereas a good deal of warping might be necessary on a small machine. The large machine can be handled more easily on the ground and can alight in smaller places.

When considered from the point of view of load to be carried or long distance to be flown the large machine has it all its own way. Where a large load is to be carried the size of the machine to do it must be increased until the useful load is sufficiently great. The size of the machine that is required for the purpose depends on the total weight per H.P. that can be carried. There is here no question of competition between large and small machines, it is a case of the correct machine for the purpose.

For future commercial developments the large machine scores with plenty of room for passengers to sit in comfort, or mails or luggage to be carried, and with its steadier movement will afford great comfort to those who travel by it. It is probable that commercial aeroplane work will be undertaken for long-distance journeys. Where delays at the commencement of the journey are a large percentage in time of that necessary to complete the distance, the possible time taken to traverse a given space may be as great or even greater than that taken by a more certain means of transit. It is the old question of the hare and the tortoise. Where, however, the distance to be traversed is great, such as 1,000 to 2,000 miles, or with journeys such as crossing the Atlantic, the passengers or mails could afford to wait a day or two and will accomplish the journey far quicker than any other means of transit. Were the commercial development of aviation confined to journeys of from 50 to 200 miles, delays at starting or the cost of organising to prevent them would cause the aeroplane's use to be considerably nullified.

It is this question of certainty in operation that requires careful attention, for it is the one thing at the present time that the aeroplane requires in order that it may take its proper place in commercial work. Engines for this will probably be more heavily built to reduce the possibility of breakdown, and multi-engine machines will be used which can fly satisfactorily even if one engine breaks down. Here again this points to the use of the larger machine.

Finally, it must be pointed out that the same improved performance can be obtained from a large machine, whether for scouting, fighting, or weight carrying, provided that the specifications are the same in both cases. It is absurd to compare the performance of a weight-carrying machine with high values of useful weight per H.P. with a small scout of very small useful weight per H.P., and particular attention is, therefore, drawn to the methods of comparison set out in Section II., so that careful comparison may result.

Curtiss Model Twin JN military tractor.

DISCUSSION.

Mr. F. W. Lanchester, chairman, in opening the discussion, said that he desired to congratulate Mr. Handley Page on his very able paper. It was perfectly true that some twelve months ago he had opposed the position forced upon aeroplane constructors by the popular clamour for the battleplane, comparable to the dreadnought, and the demand for the building of an enormous fleet of aeroplanes. For that reason he had been opposed to the large aeroplane. The present is the period of the small aeroplane. When the safety of the country depends on its armament it is rather important to go with due caution. He was heartily appreciative of the work of Mr. Handley Page, and he felt that he had the courage of his convictions. He believed the work of Mr. Page would stand as work of the greatest value to aeroplane development. On the question of the development of the engineering side especially there was room for controversy. Mr. Page said when the weight increased the structural weight did not increase proportionately. The big scale certainly altered the question when not working to the same drawings. As to whether it was more economical to build one large aeroplane or many small ones, that at present depended on the military outlook.

With regard to the various curves displayed by Mr. Page, Mr. Lanchester said everybody had his own system of curves, and thought that

Gallaudet twin motored seaplane constructed for the U. S. Navy.

THE SIMPLEX HISPANO-SUIZA MOTOR

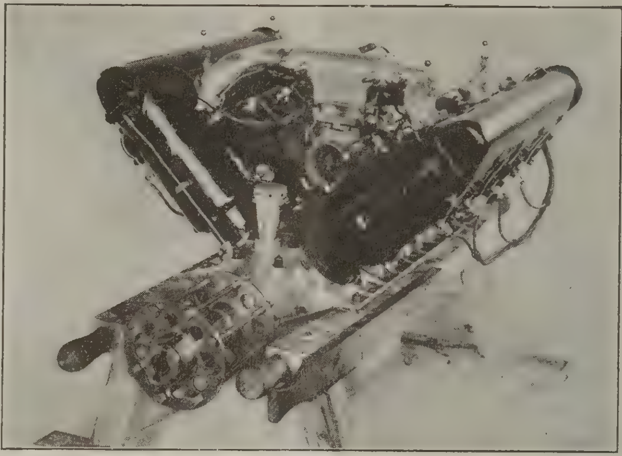
WE take pleasure in presenting this week two pictures of the Hispano-Suiza motor, constructed by the Wright-Martin Aircraft Corporation.

The motor shown is known as Model A, and develops 150 h.p. at 1450 r.p.m. It is of the water-cooled four-cycle Vee type, with eight cylinders, 4.7245 inch bore by 5.1182 inch stroke, piston displacement 718 cubic inches. At sea level it develops 150 h.p. at 1,450 r.p.m. It can be run successfully at much higher speeds, depending on propeller design and gearing, developing proportionately increased power. The weight, including carburetor, two magnetos, propeller hub, starting magneto and crank, but without radiator, water or oil or exhaust pipes, is 445 lbs. Average fuel consumption is .5 pound per horsepower hour and the oil consumption at 1,450 r.p.m. is three quarts per hour.

Four cylinders are contained in each block, which is of built-up construction; the water jackets and valve ports are cast aluminum and the individual cylinders heat-treated steel forgings threaded into the bored holes of the aluminum castings. Each block after assembly is given a number of protective coats of enamel, both inside and out, baked on. Coats on the inside are applied under pressure.

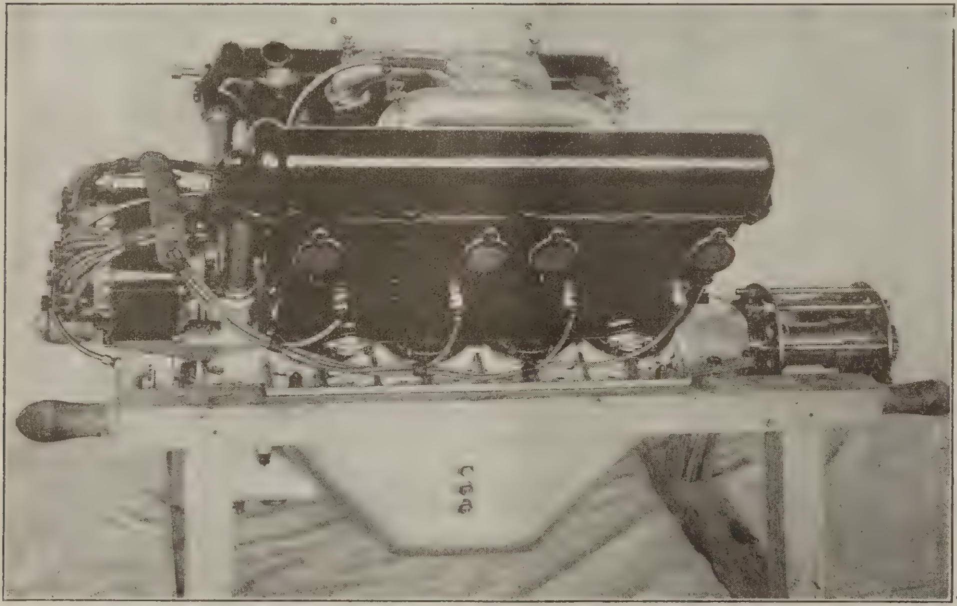
The crankshaft is of the five-bearing type, very short, stiff in design, bored for lightness and for the oiling system. The crankshaft extension is tapered for the French standard propeller hub, which is keyed and locked to the shaft. This makes possible instant change of propellers. The case is in two halves divided on the center line of the crankshaft, the bearings being fitted between the upper and lower sections. The lower half is deep, providing a large oil reservoir and stiffening the engine. The upper half is simple and provides magneto supports on extension ledges of the two main faces.

The valves are of large diameter with hollow stems, working in cast iron bushings. They are directly operated by a single hollow camshaft located over the valves. The camshafts are driven from the crankshaft by vertical shafts and bevel gears. The camshafts, cams and heads of the valve stems are all enclosed in oil-tight removable housings of cast aluminum.



Hispano-Suiza Model A

Oiling is by a positive pressure system. The oil is taken through a filter and steel tubes cast in the case to main bearings, through crankshaft to crank pins. The fourth main bearing is also provided with an oil lead from the system and through tubes running up the end of each cylinder block, oil is provided for the camshafts, cams and bearings. The surplus oil escapes through the end of the camshaft where the driving gears are mounted, and with the oil that has gathered in the top casing, descends through the drive shaft, and gears to the sump.



Hispano-Suiza Model A

(*Continued from page* 109)

everybody else ought to agree with him. He doubted whether all those present understood and agreed with the said curves.

Wing-Commander C. J. L'Estrange Malone, R.N., stated that as regards the limiting size of aeroplanes some thousands of years ago men probably argued as to whether a ship could be bigger than one man could dig out of a tree with a penknife, and the present position seemed to him somewhat analogous. He thought engineers must abolish limitations of size by introducing new materials into aeroplane construction.

Lieutenant Archibald R. Low, R.N.V.R., at the request of Commander Malone, then illustrated by lantern slides a method of calculation evolved a few years ago by a French aeronautical engineer relative to the limiting size of aeroplanes. He stated that he considered Mr. Page an "outrageous heretic," as structural weight must necessarily increase faster than the size of an aeroplane. If it did not increase actually as the cube of the dimensions, a limiting size would still be reached.

Mr. Leonard Bairstow, A.R.C.S., in the course of his remarks, during which he challenged Mr. Page's conclusions, stated that there are limitations, and there will come a time when the size of the machine increases in which you will not be able to increase the load; the load will increase more rapidly than the weight.

Captain F. S. Barnwell, R.F.C., referred to the ability of improving the structure. As large machines cannot be "chucked" about by the pilot they do not need the same factor of safety; the smaller the machine the higher the factor of safety. All theoretical curves were based on model figures for small wings at low speeds, and therefore could not be applied to larger machines. If one worked on very small model figures one went wrong on higher speeds. At present the aeroplane was purely a war machine, and the most important quality for a war machine was maneuver ability, so that for the time being the large machine was out of court. The best fighting machines were composed of the largest and lightest possible engine with the smallest possible fringe of aeroplane round it. He had a personal liking for the smallest aeroplane round the best engine.

Mr. G. Holt Thomas said that he disagreed with Mr. Page on sundry points. The large aeroplane was for the sea, where it would have unlimited space, but for military purposes he thought when carrying large loads over the land it would be better to split it up and carry it on small machines.

Mr. R. L. Howard Flanders said that when the weight per horse power of a machine was increased, the climb seemed to fall off disproportionately.

Wing Commander A. M. Longmore, R.N., said that there was plenty of room for all types, and that aeroplanes, like ships, could be classed as destroyers (scouts,) light cruisers (1½ strutters), cruisers (ordinary two-seaters) and battleships (big aeroplanes). As in warships, the armament must go up correspondingly with the big machine. Otherwise it has the same armament as the small machine. A few extra machine guns with the same range as those carried by "destroyers" were not enough. The present type of big machine with the engines and tanks spread out added, he thought, to the vulnerability of the machine. There seemed no reason why the power plant should not be centralised and well-armoured.

METHODS OF MEASURING AIRCRAFT PERFORMANCES*

By CAPT. H. T. TIZARD, R. F. C.

AEROPLANE TESTING

THE accurate testing of aeroplanes is one of the many branches of aeronautics which have been greatly developed during the war, and especially during the last year. For some months after the war began a climb to 3,000 to 5,000 ft. by aneroid and a run over a speed course was considered quite a sufficient test of a new aeroplane; now we all realize that for military reasons certainly, and probably for commercial reasons in the future, it is the performance of a machine at far greater heights with which we are mainly concerned. In this paper I propose to give a short general account of some of the methods of testing now in use at the Testing Squadron of the Royal Flying Corps, and to indicate the way in which results of actual tests may be reduced, so as to represent as accurately as possible the performance of a machine independently of abnormal weather conditions, and of the time of the year. For obvious reasons full details of the tests and methods employed cannot yet be given. So far as England is concerned, I believe that the general principles of what may be called the scientific testing of aeroplanes were first laid down at the Royal Aircraft Factory. Our methods of reduction were based on theirs to a considerable extent, with modifications that were agreed upon between us; they have been still further modified since, and recently a joint discussion of the points at issue has led to the naval and military tests being co-ordinated, so that all official tests are now reduced to the same standard. It should be emphasized that once the methods are thought out scientific testing does not really demand any high degree of scientific knowledge; in the end the accuracy of the results really depends upon the flyer, who must be prepared to exercise a care and patience unnecessary in ordinary flying. Get careful flyers whose judgment and reliability you can trust and your task is comparatively easy; get careless flyers and it is impossible.

At the outset it may be useful to point out by an example the nature of the problems that arise in aeroplane testing. Suppose that it is desired to find out which of two wing sections is most suitable for a given aeroplane. The aeroplane is tested with one set of wings, which are then replaced by the other set, and the tests repeated some days later. The results might be expressed thus:—

	A Wings.	B Wings.
Speed at 10,000 ft.	90 m.p.h.	93 m.p.h.
Rate of climb at 10,000 ft.	250 ft. a minute.	300 ft. a minute.

Now, the intelligent designer knows, or soon will know, that, firstly, an aneroid may indicate extremely misleading "heights"; and, secondly, that even if the actual height above the ground is the same in the two tests, the actual conditions of atmospheric pressure and temperature may have been very different on the two days. He will therefore say, What does that 10,000 mean? Do you mean that your aneroid read 10,000 ft., or do you mean 10,000 ft. above the spot you started from, or 10,000 ft. above sea-level? If he proceeds to think a trifle further he will say, What was the *density* of the atmosphere at your 10,000 ft.; was it the *same* in the two tests? If not, the results do not convey much. There he will touch the keynote of the whole problem, for it is on the density of the atmosphere that the whole performance of an aeroplane depends; the power of the engine and the efficiency of the machine depends essentially on the density, the resistance to the motion of the machine through the air is proportional to the density, and so finally is the lift on the wings. None of these properties are proportional solely to the pressure of the atmosphere, but to the density—that is, the weight of air actually present in unit volume. It follows that it is essential when comparing the performances of machines to compare them as far as possible under the same conditions of atmospheric *density*, not as is loosely done at the same height above the earth, since the density of the atmosphere at the same height above the earth may vary considerably on different days, and on the same day at different places.

At the same time, in expressing the final results, this principle may be carried too far. Thus, if the speed of a machine were expressed as 40 metres a second at a density of 0.8 kilogs. per cubic metre, the statement, though it may be strictly and scientifically accurate, will convey nothing to 99 per cent. of those directly concerned with the results of the test. The result is rendered intelligible and, indeed, useful by the form "90 m.p.h. at 10,000 ft.," or whatever it is. With this form of statement, in order that all the statements of results may be consistent and comparative, we must be careful to mean by "10,000 ft." a certain definite density—in fact, the average density of the atmosphere at a height of 10,000 ft. above mean sea-level. This is what the problem of "reduction" of tests boils down to: what is the relation between atmospheric density and height above sea-level? This knowledge is obtained from meteorological observations. We have collected all the available data, mostly unpublished, with results shown in the following table:—

TABLE I.—*Mean Atmospheric Pressure, Temperature and Density at various Heights above Sea-Level.*

Height in Kiloms.	Height in equivalent feet.	Mean pressure in millibars.	Mean temp. in absolute degrees Centrigrade.	Mean density in kgm. per cubic metre.
0	0	1,014	282	1.253
1	3,280	900	278	1.128
2	6,560	795	273	1.014
3	9,840	699	268	0.909
4	13,120	615	262	0.818
5	16,400	568	255	0.735
6	19,680	469	248	0.658
7	22,960	407	241	0.589

These are the mean results of a long series of actual observations made mainly by Dr. J. S. Dines. It is convenient to choose some density as standard, call it unity, and refer to all other densities as fractions or percentages of this "standard density." We have taken, in conformity with the R.A.F., the density of dry air at 760 mm. pressure and 16° C. as our *standard density;* it is 1.221 kilog. per cubic metre. The reason this standard has been taken is that the air speed indicators in use are so constructed as to read correctly at this density, assuring the law: $p = \frac{1}{2}\rho V^2$, where V is the air speed, p the pressure obtained, ρ the standard density.

In some ways it would doubtless be more convenient to take the average density at sea-level as the standard density, but it does not really matter what you take so long as you make your units quite clear. Translated into feet, and fraction of the standard density, the above table becomes:—

TABLE II.

Height in feet.	Percentage of standard density.	Height in feet.	Percentage of standard density.	Height in feet.	Percentage of standard density.
0	102.6	7,000	81.9	15,000	63.0
1,000	99.4	8,000	79.2	16,000	61.1
2,000	96.3	9,000	76.5	†16,500	60.1
3,000	93.2	†10,000	74.0	17,000	59.1
4,000	90.3	11,000	71.7	18,000	57.1
5,000	87.4	12,000	69.5	19,000	55.2
6,000	84.6	†13,000	67.3	20,000	53.3
†6,500	83.3	14,000	65.2		

Let us briefly consider what these figures mean. For example, we say that the density at 10,000 ft. is 74 per cent. of our standard density, but it is not meant that at 10,000 ft. above mean sea level the atmospheric density will always be 74 per cent. of the standard density. Unfortunately for aeroplane tests this is far from true. The atmospheric density at any particular height may vary considerably from season to season, from day to day, and even from hour to hour; what we do mean is that if the density at 10,000 ft. could be measured every day, then the *average* of the results would be, as closely as we can tell at present, 74 per cent. of the standard density.

The above table may therefore be taken to represent the conditions prevailing in a "normal" or "standard" atmosphere, and we endeavor, in order to obtain a strict basis of comparison, to reduce all observed aeroplane performances to this standard atmosphere, *i.e.,* to express the final results as the performance which may be expected of the aeroplane on a day on which the atmospheric density at every point is equal to the average density at the point. Some days the aeroplane may put up a better perfomance, some days a worse, but on the average, if the engine power and other characteristics of the aeroplane remain the same, its performance will be that given.

It must be remembered that a standard atmosphere is a very abnormal occurrence; besides changes in density there may occur up-and-down air currents which exaggerate or diminish the performance of an aeroplane, and which must be taken carefully into account. They show themselves in an otherwise unaccountable increase or decrease in rate of climb or in full speed flying level at a particular height.

We now pass to the actual tests, beginning with a description of the observations which have to be made and thereafter to the instruments necessary. The tests resolve themselves mainly into (*a*) A climbing test at the maximum rate of climb for the machine. (*b*) Speed tests at various heights from the "ground" or some other agreed low level upwards.

Experience agrees with theory in showing that the best climb is obtained by keeping that which is frequently called the air speed of an aeroplane, viz., the indications of the ordinary air speed indicator, nearly constant whatever the height—in other words, ρV^2 is kept constant. We can look at this in this way. There is a limiting height for every aeroplane above which it cannot climb; at this limiting height, called the ceiling of the machine, there is only one speed at which the aeroplane will fly level, at any other air speed higher or lower it will descend. Suppose this speed be 55 m.p.h. on the air speed indicator. Then the best rate of climb from the ground is obtained by keeping the speed of the machine to a steady indicated 55 m.p.h. Fortunately a variation in the speed does not make very much difference to the rate of climb; for instance, a B.E.2c with a maximum rate of climb at 53 m.p.h. climbs just as fast up, say, 5,000 ft. at about 58 m.p.h. This is fortunate as it requires considerable concentration to keep climbing at a steady air speed, especially with a light scout machine; if the air is at all "bumpy" it is impossible. At great heights the air is usually very steady, and it is much easier to keep to one air speed. It is often difficult to judge the best climbing speed of a new machine; flyers differ very much on this point, as on most. The Testing Squadron, therefore, introduced some time ago a rate of climb indicator intended to show the pilot when he is climbing at the maximum rate. It consists of a thermos flask, communicating with the outer air through a thermometer tube leak. A liquid pressure gauge of small bore indicates the difference of pressure between the inside and outside of the vessel. Now, when climbing, the atmospheric pressure is diminishing steadily; the pressure inside the thermos flask tends therefore to become greater than the outside atmospheric pressure. It goes on increasing until air is being forced out through the thermometer tubing at such a rate that the rate of change of pressure inside the flask is equal to the rate of change of atmospheric pressure due to climbing. When climbing at a maximum rate, therefore, the pressure inside the thermos flask is a maximum. The pilot therefore varies his air speed until the liquid in the gauge is as high as possible, and this is the best climbing speed for the machine.

What observations during the test are necessary in order that the results may be reduced to the standard atmosphere? Firstly, we want

(*Continued on page* 117)

[*] *Paper read before the Aeronautical Society of Great Britain on March 7th.*

[†] *6,500 ft. is introduced as corresponding roughly to the French test height of 2,000 metres. 10,00 ft. similarly corresponds roughly to comparing aeroplane test performances to the French standard of 3,000 metres, and similarly for 13,000 and 16,500 ft.*

THE 200 H. P. MAYBACH ENGINE

In several recent issues of the Automobile Engineer there have been presented parts pertaining to German aero engine development which are particularly interesting at this time. There is little doubt that the information set forth, while being of considerable interest to the majority of our readers, will be particularly so to such as are engaged upon, or associated with, aircraft engine production.

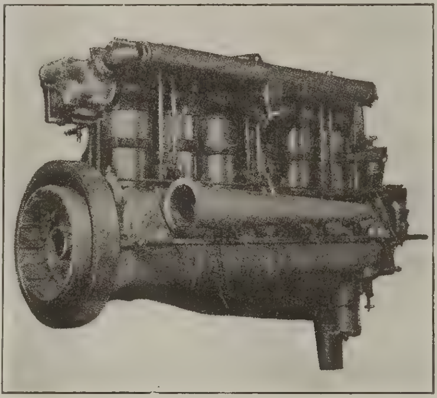
Our first, and present, description is of the Maybach engine, as fitted to the Schutte Lanz and Zeppelin airships. This engine is probably of the latest Maybach design, and presents many interesting features, although main interest really centres around the parts that are more in the nature of accessory fittings, made necessary or advisable by the particular application of the engine, viz., airship propulsion. Before proceeding to describe the engine and its accessories in detail, a general outline of the function and layout of the more unusual fittings will doubtless be of interest.

Instead of regarding each portion of the engine accessory system as a separate item, it will probably be simpler to regard each fitting as a separate item in reviewing its purpose in the general layout, and also to confine our attention at the moment to those parts not usually found on an aircraft engine.

Referring to the general diagram of the oil and gasoline pressure system (fig. 1), it will be seen that in the top left-hand corner there are two pumps driven by a common crank that is attached to a shaft, this shaft being worm gear driven off the engine crank. The horizontal pump is that for the fuel, and it will be noticed that the valves of this pump are far removed from the pump itself, being located at the base of the chamber seen at the bottom left-hand corner of the general diagram. The reason for this arrangement is the practical impossibility of pumping liquid petrol, so that a column of air has been interposed between the pump and the petrol itself. It will be noticed that the fitting containing the petrol pump valves also carries the oil filter, of course, definitely divided off, but incorporated in the body of the same fitting. The reason for this is most probably that it happened to be convenient to embody the two in one. There does not seem to be very much reason to suppose that the two are combined with a view to warming the petrol and alternately cooling the oil. Its position on the engine is denoted by the letter A in the general arrangement diagram of the engine (fig. 2).

The fitting shown at the right-hand bottom corner of fig. 1 is really merely the float chamber of the carbureter. It functions somewhat differently, as it is arranged to operate at varying altitudes, but in effect it serves the purpose of a float chamber to feed the carbureter reservoir. Its position relative to the engine is shown at B in fig. 2, and it has probably been located in the position shown from motives of safety, as evidently, in the position shown in the general diagram, danger arising from a float chamber near to the engine is avoided.

With reference to the oil system, this is made clear in a detailed description following, and calls for no special note at this point, except as regards the control that the oil pressure exercises over the fuel supply. This control is clearly shown to the right in the diagram (fig. 1), where connection will be seen between the jet damper and an oil controlled vertical piston. This piston is under oil pressure, and serves merely to hold out of action a stop that controls the jet cut-off, so that as long as the oil pressure maintains the fuel supply continues. When the oil pressure drops below a predetermined limit, the piston rises under the influence of its spring, releasing a catch and so closing the jet. Oil to this fuel controlling piston is distributed through a centrifugally-governed piston valve that is adjustable externally, the oil being throttled by means of an adjusting lever that limits the travel of the piston valve, so that by the setting of the lever, the actual oil pressure in the lubricating system is determined. This explanation does not quite coincide with the positions assigned to the oil piston valves and ports in another diagram, but the present diagram (fig. 1) gives a satisfactory explanation of the principle of the control. Evidently the piston controlling the fuel cut-out stop can, by so arranging the strength of its spring, be given a certain range of action; that is to say, it can be designed to maintain its position and hold off the fuel stop between any range of oil pressure required, say, from 5 lb. minimum to 35 lb. maximum, according to the strength of the spring, which merely needs to be strong enough to overcome the minimum pressure decided upon, as it is not until oil pressure drops that there is any necessity for cutting off the fuel.



The 200 H. P. Maybach

The carbureter, which is shown in the top right-hand corner of the diagram (fig. 1), needs no general explanation at this stage, and will be described in full detail later. The small oil radiator, together with the system of filters beneath it, are simply the oil cooling and filtering circuit, and, as a matter of fact, it is believed that these were, by a curious whim of the chief engineer, generally cut right out of service when the airships were in use.

The engine starting mechanism consisted of a pump and the necessary mechanism for filling the cylinders with mixture, which was ignited by a geared-up hand starter. Fuller details of this system are given in the following pages.

With regard to details of the engine itself, the bore is 150 mm., the stroke 190 mm., and the compression ratio 5.94 to 1; the normal b.h.p. is estimated as 200 at 1,200 r.p.m. Each of the six cylinders is a separate unit, consisting of a steel cylinder, screwed into a malleable cast iron head and jacket casting, containing the valve seatings. The cylinder barrel is provided with a rectangular groove about half-way down, into which is fitted the packing material forming the water-jacket joint. The material used in making the water joints is probably asbestos, clamped into position by several turns of copper wire, wound round the cylinder barrel inside the machined groove. A variation of this joint is evidently in use, as on a cylinder carried on the Zeppelin as a spare a large union nut was employed at the flange, and a plain joint used in the cylinder head. The cylinder barrel is hardened at its base, or holding-down flange, presumably for the purpose of strengthening it.

Five valves per cylinder are arranged, the two inlet ports being 48 mm. diameter and the exhaust ports 35 mm. diameter. The exhaust valves are situated on the left-hand side of the engine looking from the flywheel and propeller end, and all the valves are of the overhead type, working vertically in the water-cooled cylinder head, and operated by rocker arms. All the three valve rocker arms for the exhaust valves are in one stamping, and are operated by one push rod. Similar construction and actuation are adopted for the inlets, the push rod ends being cupped, and the rockers and tappets arranged with spherical heads to correspond. The rocker arms are on hollow spindles supported on brackets bolted to the cylinder heads. No adjustment is provided other than the adjusting screw on each valve rocker arm.

The valve gear is operated by two camshafts, one on either side of the crankshaft. There are driven by gears inside the crank case at the flywheel end. Cam rollers are fitted to the tappets in the usual manner.

The large circular water joint between each of the six cylinders is made by a 6½-in. diameter rubber and wire ring about ½-in. thick, encircled by a hand clip of sheet brass. This clip, when screwed up, reduces the diameter of the packing ring, causing the rubber to expand, thus making a simple face joint against the two machined faces of the water jacket. Water cooling is by a pump working vertically inside the water lead to the front cylinder in an extension of the crank case casting. The pump spindle with vane shown in fig. 3, is driven directly off the crankshaft bevel gear at twice the speed of the engine; its position is shown at C in fig. 2.

The diameter of the water inlet pipe leading from the radiator to the crank case extension is

Top View of Maybach Engine

2¼ inches. Water from the pump enters the aluminum water jacket surrounding the front carbureter, which is attached to the 6½-in. water joint flange of the front cylinder, and thence the water flows through all the cylinder jackets and, circling the water jacket of the other carbureter attached to the flange of the rear cylinder, enters the copper water jacket surrounding the exhaust manifold, whence a return pipe leads back to the radiator. The crank case is internally scavenged and cooled by inducing a current of air, as shown in fig. 4. A marine-type cowl that projects throug the roof of the gondola leads direct to a large aluminium pipe, tapering in diameter, arranged externally beside the crank case and communicating with it by six short branches.

Attached to the crank case in a similar position on the opposite side are six breathers, or gauze-covered ventilators, that stand vertically and flat against the crank case. The arrangement of this breathing or scavenging is as shown in fig. 4, but it should be noted that the cowl opening is towards the rear of the ship, so that scavenging takes place by suction induced by the ship's motion.

The cylinder holding-down bolts are pegged into the crank case casting at the top, and are provided with flanges, so that the bearing caps are not disturbed when the cylinders are removed, as the holding-down bolts pass right through the crank case top half in the usual manner. Each cylinder is held down by four clamps or dogs.

With regard to lubrication, oil is drawn by the vertical oil pump (figs. 1 and 5) from the oil service tank D (fig. 2), situated below the crank chamber, through the check valves directly below the pump piston by a pipe leading to the two vertical filters P, whence the oil is led into the top of the small oil cooler or radiator G (fig. 1). This cooler is situated outside the gondola.

After passing through the cooler, the oil returns through the main oil filter K to the main bearings. The main bearings can also be lubricated direct from the pressure pump, cutting out the oil cooling system by the cocks below the filters P.

The surplus oil returns to the service tank through the relief pressure valve E.

All the valve rockers are lubricated under pressure through hollow spindles coupled together between the cylinders by rubber connections and clips. The oil enters at one end of the rocker arms through a pipe leading from the main oil supply, and passes through the hollow spindles of the inlet rocker arms, and returns along the exhaust valve rocker spindles to the base chamber. The oil in the crank case returns to the service tank by two large drain passages leading directly from the bottom of the crank chamber into the service tank below.

The six-throw crankshaft runs on seven plain bearings, the diameter of the journals and the crank pins being 66 mm. The journals are bored with a 40 mm. hole, and the crank pin with a 36 mm. hole, the ends of the latter being plugged by aluminium oil catcher troughs clamped together by a 7 mm. bolt through the hollow crank pin. The weight of the complete crankshaft with camshaft driving pinion and bevel gear for driving the water pump, etc., is about 99 lb.

The pistons are of cast iron, fitted with three rings above the gudgeon pin, each piston weighing, complete with gudgeon pin and rings, 10.84 lb. The gudgeon pin is 38 mm. diameter, and is located by a set screw, screwed vertically into the pin from the bottom of the gudgeon pin boss inside the piston and locked with a split pin inside the hollow gudgeon pin.

The connecting rods are square section externally, 33 mm. each way, and are bored up the centre with a 26 mm. hole, through the centre of which an 11 mm. pipe is fixed, leading from the big end bearing to the gudgeon pin bush for lubricating the small end.

Each engine is fitted with two separate carbureters, situated at either end of the engine itself. They are attached to the water jackets of the end cylinders by the water jacket flanges. A sketch arrangement of the carbureters showing the position of the jet, throttle valve, and constant head jet reservoir, and also the water jackets, is shown in fig. 6.

The large cylindrical wire gauze baffle adjacent to the carbureter, and at the end of the induction pipe shown in the sketch, is presumably to stop firing back into the carbureter. It might also further break up the mixture.

A detailed account of the working of the carbureter, with its unusual system of fuel supply, will doubtless be of interest, and in fig. 7 is given a diagram of the carbureter, that has been prepared to show the observed interior construction. The carbureter consists of the following parts: A barrel throttle, a main air regulator, a jet, and damping device, and a constant head gravity gasoline feed reservoir.

The rotary barrel throttle opens on one side to the inlet pipe, on the other to a mixing chamber. In the lower portion of the barrel is a large extra air port registering with a port in the casing. The size of this port is further controlled by an air shutter (not shown).

The main air regulator is of the sliding shutter or guillotine type. It opens or shuts as the throttle opens or shuts, being interconnected by bell crank levers.

The jet has an eccentric hole covered by a cap, also with an eccentric hole, so that rotation of the cap regulates the area of the jet hole. The arrangement appears similar in action to the jet of the White and Poppe carbureter. The jet cap is also interconnected with the throttle and air slide, opening when they open, and *vice versa.*

The jet damping device is interconnected with the lubrication system, but might have been operated separately, if desired.

The constant head gravity petrol feed to the jet, in lieu of the usual and adjacent float feed, is provided by a small reservoir placed a little higher than the jet, that is fed from the float chamber, in turn fed from the pump and the separate air vessel or valve box.

It may be safely assumed that the operation of the carbureter, so far as carburation is concerned, is the same as in the White and Poppe; that is to say, the quality of the mixture is, at any throttle opening, kept constant by mechanical means, *i.e.*, the interconnection of the throttle air and jet orifices, as shown in fig. 9. Means of adjustment of the relative setting of these three are provided.

FOREIGN NEWS

BELGIUM.

King Albert of Belgium recently made a long airplane flight under fire over the fighting front, according to *La Metropole.* While visiting a new flying ground the King expressed a desire to act as an observation officer. Accordingly he ascended with the famous Belgian airman, Captain Jacquet, at 8:15 P. M. Preceded by a squadron of fighting planes the King flew over the whole Belgian-Yser front at a height of 3,000 to 6,000 feet. He made many observations and took photographs with success.

German anti-aircraft guns kept up a sustained fire, but no German airman ventured in the way of the King's aeroplane. Subsequently the King discussed his observations with the General Staff.

Henry E. Montgomery Suckley of Rhinebeck, N. Y., in charge of the Stock Exchange unit of the American Ambulance Field Service, was killed recently while on duty near Saloniki, according to a cable received by his uncle, H. E. Montgomery of 80 Broad street. The cable announcing his death came from General Sarrail, commanding the Allied troops at Saloniki, and was transmitted by Mr. Galatti, the second in command of the American Ambulance Field Service in Paris.

"Suckley," the General cabled, "was seriously wounded by an aeroplane bomb yesterday, and died this morning. He is proposed for the Legion of Honor."

Mr. Suckley was born in Orange, N. J., thirty years ago, and was a son of Robert B. Suckley of Rhinebeck, N. Y. Mr. Suckley graduated from Harvard in the class of 1910. He has served in the American Ambulance almost from the start of the war. After serving in the Vosges he was early in 1916 transferred to Pont-á-Mousson, and he was there until June of that year.

FRANCE

Miss Ruth Law, the American aviatrice who is in Paris studying the developments of aviation in France during the war, said to a correspondent for the European edition of the *Herald:*

"At Le Bourget I was simply astounded at the number of aeroplanes which have guarded Paris since the war and the different types of machines. If we combine all the aviation fields of America and call together all our aeroplanes, both military and privately owned, the display would not compare with that at Le Bourget, and, of course, there are many others in France.

"I came to France hoping to investigate the various makes of French aeroplanes and to buy the fastest machine made, but, of course, France is making no machines now except for military purposes, so I have no chance to determine which type of French machine I would prefer.

"I was very much surprised to find that the women of England have not taken up aviation to a greater extent. English women have always had the reputation of taking up all outdoor sports more seriously than American women, so I was disappointed to find few English women aviators."

Miss Law is coming home to take part in the race from San Francisco to New York in June, to be held under the auspices of the Aero Club of America. She says that her visit to England and France has been a great lesson to her and has given her many new ideas.

Lieutenant William Thaw, the American aviator, has won another citation in French army orders for a brilliant bit of work in the course of the German withdrawal from France. Thaw, while flying low on a reconnoitering expedition one day, discovered a large detachment of Germans who were protected by a screen of trees. They evidently formed the rear guard, left to cover the retreat of the main body.

Thaw swooped down and emptied his machine guns among the Germans at close range. Then he returned to his own lines and reported to the French cuirassiers, whom he directed to the German ambush, swooping down again to join in the attack.

Lieutenant Sweeney, another American who has won a commission in the French army, like his compatriots who are serving France has been eagerly studying the position of the United States with regard to the war. He tells the *New York Sun* correspondent that the French War Department, recognizing as natural the wish of American volunteers to serve with any American expeditionary force which may come to this country, has promised to release him within twenty-four hours if war between the United States and Germany is declared.

This is in line with the department's practice since the start of the European war. British volunteers were permitted to join the British expeditionary force, Belgians to join the Belgian army and Italians who were fighting under the younger Garibaldis to join the Italian army after Italy declared war.

The newspapers of Besancon say that German aeroplanes are dropping on French territory objects quite inoffensive in appearance, but which are in reality of the utmost deadliness.

Candy containing germs of epidemic diseases, fatal to any person eating it, and handbags and pocketbooks filled with dangerous explosives, which detonate on contact, have been cast down by German fliers, these newspapers declare.

GREAT BRITAIN

Of the many developments during the present war, nothing has equalled that of aviation. When the war began the various aviation services, by comparison with what they are now, amounted to little with respect to numbers of machines, numbers of aviators, the character of flights and the various uses to which these services are now put daily.

This rapid development is still going on. Greater than the fact that the aircraft now daily perform duties hardly thought of prior to the war is the one that any slackening in the development of the material used inevitably leads to falling behind the enemy.

The designers and builders must be constantly at work on improvements or the aviators at the front will soon find themselves in machines inferior to those of the enemy, and therefore unable to maintain the air superiority if they have it, or to obtain it if they have not.

The same evil will result if the number of machines, with, of course, the number of pilots and observers is not constantly increased.

At one time on the Somme the British maintained their air superiority with an inferior machine because they had sufficient numbers. A number of times in this war the air superiority has passed from one side to another because of the sudden appearance at the front of a superior type of machine.

In the beginning of the war the few aviators belonging to each army tried to perform in a general way the various duties assigned to them.

As the war progressed, and not only the value but the downright necessity for the continued use of aircraft became evident, it was soon seen that the service would have to be divided into various branches, depending upon the duty to be performed, and that these various duties demanded various types of machines, and frequently a variation in the training of some of the personnel manning them.

On land the duties at present may be divided into reconnoissance both in a war of movement, such as recently took place in Roumania or in a war of position such as that now going on along the French front; the observation of artillery fire both for ranging and combat; the preservation of the liaison between the infantry and the artillery during an attack: the preservation of the liaison between the general in comamnd of the unit and his troops in action; combat with other machines, with dirigibles; captive balloons and troops, and the attack on enemy depots and factories by raiding and dropping bombs on them.

Under normal conditions most, if not all of these various duties are being performed daily, not only in one part of the long lines on which the troops of the contending Powers face each other but on all parts.

The number of machines and pilots possessed by each Power is not, of course, published. However, it can be readily seen that the figure for any one great Power easily mounted into the thousands.

Aside from the nomal wear and tear, due to hard usage, there are the losses due to battle which have to be made good. During 1916, the English and French brought down about 900 German machines on the western front, to say nothing of eithy-one captive observation balloons.

The month of September, in which the fighting was heavy, saw the fall of 100 of these. When it is considered that, aside from these normal losses in material which have to be made good, the introduction of a new and better type of machine means the prompt replacement of a large part of the material, some idea can be gained of the tremendous construction which must go on.

As the power of aircraft increases the raids are carried further and further into enemy territory. This means that all important factories, depots and cities back of the zone of the armies must have aircraft defence.

While anti-aircraft guns can and do make such attacks difficult and dangerous, the only certain and real defence is a sufficient number of aircraft promptly to meet attack and drive back or defeat the invader.

Due to the fact that the weight of explosive which can by carried by any one machine is comparatively small and that a few hits, even though successful, produce little result, the number of machines sent on a raid is constantly increasing.

The number used for defensive purposes at the various points in danger of being raided must, therefore, also increase. The increase in the number of machines and the making good of casualties demands a considerable increase in the number of pilots and other personnel.

The various duties to be performed by the personnel require the establishment of schools in which the careful training necessary can be had. These schools, of course, must have machines, instructors, mechanics and other personnel.

From all this it is easily seen that, from being a minor auxiliary service, aviation has reached a point where it can be considered to be a separate branch of the service. There is every indication that a still more tremendous development will take place.

At the present time in the American army the aviation service, which has only few machines and a small number of pilots, is merely a branch of the Signal Corps, one of the auxiliary services of the army. To bring it up to the point of the French, British or German aviation service would require an immense increase in material and personnel.

Should we take their present status as the standard to be struggled for, we would find ourselves on reaching it still far behind, because these services are going to continue their development until the end of the war, and whatever point they will have reached at that time will merely be considered the starting point for their development in preparation for the next war.

In other words, if we are to have an aviation service which will put us on a par with the great Powers, we should start immediately to build up a service which with respect to amount of material, number of personnel, and development of better types of machines is considerably in excess of anything now in existence.

Model Gliders

A model glider represents the initial or elementary stage of model aviation just as a power-driven model represents the most advanced. A great deal can be learned from them, and they are and always will be worthy of careful study. It is said of the great Sir Isaac Newton that later on in life he regretted that he had not studied Euclid with that attention which so worthy a writer undoubtedly deserved. The story is that he had not studied him at all, but regarded his work to be of such an elementary character as to be self-evident. The moral of this story is obvious. If the greatest minds regret in later life a previous contempt for elementary things, how ill can the ordinary individual afford to neglect them with impunity. Of all the model gliders that we have experimented with we know none that surpasses the little Burge Webb glider. "In "Flying and Some of Its Mysteries," some eighteen or nineteen entirely distinct experiments are related that can be performed with it.

It may be as well to point out that a model glider is a very sensitive and delicate piece of apparatus indeed, and one which requires the most careful handling if good results are to be expected. The wings should never be handled if possible, but the machine carried, launched, and picked up by the backbone. Always be careful not to destroy or alter any crease or fold that the wing surface may possess. With fair treatment even a paper glider will last quite a long time, but we regret to have to say that most model gliders receive anything but fair treatment.

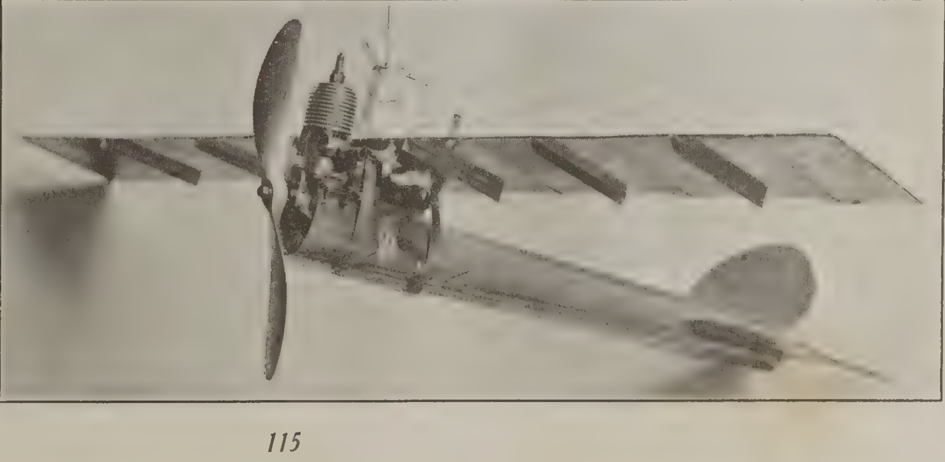
Another point in which due care must also be exercised is not to attempt to deduce too much re*stability in general,* from experiments made with such models in the (comparatively speaking) still air of a room. In the past dozens of patents and provisional specifications have been taken out on the sole strength of such experiments with the result that the patentees have, in by far the majority of cases, wasted both their time and money. Presuming, for the sake of argument, that you have, after a large number of experiments made with a small glider indoors, finally evolved a design which does seem worth something, the next step is to try it out of doors, on a considerably larger scale, *i.e.,* a minimum span of 4 ft. at least; at first in light breezes, and then in a high wind. Presuming it still successful, you would test it further by giving the model much longer flights, by suspending it from a kite some two or three hundred feet up and releasing it from the same. Again, presuming the result to be satisfactory, you would finally turn your glider—your (so-called) motorless aeroplane—into a motored one, *i.e.,* a model aeroplane carrying its own motor and propeller. The last test is an absolutely essential one; it is a natural conclusion to come to that if a model glider showing high stability glides well, it will also, when fitted with a motor and propeller, fly well and still show good stability. This by no means follows, however; so far as the loaded elevated-type of model is concerned, if it does not glide well when projected with its flight velocity, it is quite certain it will not be a successful flyer; but it does not of necessity follow that because it glides well (carrying, of course, its motor and propeller) it will also fly well. Though it would perhaps be fairly accurate to say that in the type alluded to it generally does so. In the tractor type of model it by no means follows that if the machine glides well it will also fly well—I have seen very many instances in which it did not do so. Nor is the converse true that if it flies well it will also glide well (to earth) when the propeller stops. Generally it does not do so—the aeroplane losing a certain proportion of its lift due to propeller blast—dives more or less steeply to earth. The reader must not conclude from this that a tractor model cannot be made to both fly and (if the handling be made against the breeze) also to glide to earth—because I have seen one model at any rate that does it—but it is a notable exception. I cannot agree with the correspondent in last week's issue that monoplanes make less satisfactory gliders than biplanes. It is quite a common thing for a paper glider to make several successful flights and then refuse to do any more. The explanation being that either one of the falls or improper handling has slightly altered its configuration, etc., and the conditions for a successful glide are no longer present. Naturally each particular glider has its own particular velocity at which it glides best.

Model Work in Tasmania

Doubtless many American model fliers will be glad to learn of the far reaching influence of the model aeroplane. This fact is clearly illustrated in the following letter from Mr. Clarence Arnott, Tasmania:

"I am a keen experimenter in aircraft, and have constructed and designed eight tractor machines, six being monoplanes and two biplanes, which have flown from 50 to 70 yards, hand launched, which is very good considering it is always blowing over here. The general public do not take any interest in models over here. They think because a few of us are interested in aviation that we are a bit *soft.* You will excuse this slang, but it is a fact. But we are going to show them what we really can do later on."

All steel model equipped with ½ H.P. gasoline engine, the product of the Weiss Mfg. Company. This model was exhibited at the Aero Show by the Buck Aircraft & Munitions Corp., and somewhat represents the large machine which they contemplate constructing in the very near future.



Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

The Diary of an Aviation Student

April 1st.

Went out to Mineola Flying field today with Ethel. Saw various pilots go through death-defying manoeuvers. Great admiration on the part of Ethel. If I wish to make her admire me, *must* learn to fly.

April 2nd.

Made application to aviation school and made out will.

April 3rd.

Parted with four hundred dollars for tuition, and promised thirty-one friends to take them aloft on my first flight. (Still, by the time I have learned to fly there will be aeroplanes capable of carrying that many people).

April 4th.

Went to store and purchased complete regalia for flying, and had pictures taken. Great mirth on part of cashier in photographer's.

April 5th.

Ethel pleaded with me not to risk my life. My chest swelled with determination, (while my heart quaked with fear), and I scoffed at her fears, saying that if I were killed, it would be a patriotic death, as our country needs aviators. Great admiration, and many tears on part of Ethel.

April 6th.

Went down to aviation field, to fly. Put to work in shop polishing wing struts. Made objection. Objection overruled. Stepped through a wing section and received bill for eighty-five dollars. Flying has lost some of its fascination.

April 7th.

Made flight! Confidentially must admit that I was paralized with terror. Came down, and was about to resign from school when Ethel approached, and said that although I looked pale, she could see strong determination in my face. Tried to look determined but succeeded only in looking surly.

April 8th.

Ethel brought automobile party down to see me fly. (That is, to see me taken aloft by the instructor). Great admiration on part of women, and disgust on part of men. Tried to look nonchalant but succeeded in looking cynical. While I was talking to girls, instructor comes up, and tells me to go into hangar and change the tires. Wanted to object but showed by face that I was humoring him. I hate the man! Got tires changed, and was about to go up when instructor changed his mind and took up some Japs. Spent balance of afternoon doping wings. Automobile party all left in disgust. No more so than I.

April 8th.

Pictures finished. Look like North Pole Explorer in aviation suit. Paid for pictures amid more mirth of cashier. Took pictures from pocket of Carlstrom landing from Chicago, and tried to look like Carlstrom. Mirth of cashier changed to unadulterated admiration.

April 9th.

Learned to say "Bus" instead of aeroplane. Practiced it for an hour to learn to say it unconsciously. Still feel rather foolish.

April 10th.

Made another flight. Took controls for landing. Had controls but not control. Consequence, badly damaged machine. Bill for nine hundred dollars. Refused to pay bill. Put in jail. Paid bill. Let out of jail. Resigned from Aviation School. Resignation accepted. Gave head instructor bawling out and left. (Rather precipitously.)

May 31st.

Received invitation to wedding. Ethel and Head Instructor. Going out to drown my sorrows.

June 4th

Seated at club. Not such a bad world after all!

Finis.

The Way News Travels

We vouch for the following, having heard it from a man lately returned from the front. It traces the report of the fall of Antwerp, starting in a French paper, Le Matin, and continuing through the columns of other papers.

Le Matin.

It is reported that when Antwerp was taken by the Germans, the church bells were rung in Berlin.

London Paper.

It is reported by our contemporary, Le Matin, that when Antwerp was taken by the Germans the citizens were forced to ring the cathedral bells in celebration.

Russian Paper.

We hear from our London contemporary, ——— that when Antwerp fell the Belgian priests were forced to ring the church bells in celebration.

Spanish Paper.

According to the ————— of Petrograd, when the town of Antwerp was taken, the Belgian priests who refused to ring the church bells were deported to Germany.

Le Matin. (Three months later.)

We read in our Spanish contemporary, the —————, that when the Belgian priests refused to ring the church bells at the fall of Antwerp, they were lined up against the wall and shot!

(*Continued from page* 111)

the time from the start read at intervals, and the height reached noted at the same time. Here we encounter a difficulty at once, for there is no instrument which records height with accuracy. The aneroid is an old friend now of aeronauts as well as of mountaineers, but although it has often been tentatively exposed, it is doubtful whether 1 per cent. of those who use it daily realize how extraordinarily rare it is that it ever does what it is supposed to do, that is, indicate the correct height above the ground, or starting place. The faults of the aeroplane aneroid are partly unavoidable and partly due to those who first laid down the conditions of its manufacture. An aneroid is an instrument which in the first place measures only the *pressure* of the surrounding air. Now if p_1 and p_2 are the pressures at two points in the atmosphere, the difference of height between these points is given very closely by the relation, $h = \theta \log_e p^1/_{p2}$ where θ is the average temperature, expressed in "absolute" degrees, of the air between the two points. It is obvious that if we wish to graduate an aneroid in feet we must choose arbitrarily some value for θ. The temperature that was originally chosen for aeroplane aneroids was 50° F. or 10° C. An aneroid, as now graduated, will therefore only read the correct height in feet if the atmosphere has a uniform temperature of 50° F. from the ground upwards, and it will be the more inaccurate the greater the average temperature between the ground and the height reached differs from 50° F. Unfortunately 50° F. is much too high an average temperature; to take an extreme example, it is only on the hottest days in summer, and even then very rarely, that the average temperature between the ground and 20,000 ft. will be as high as 50° F. On these very rare occasions an aneroid will read approximately correctly at high altitudes; otherwise it will always read too high. In winter it may read on cold days 2,000 ft. too high at 16,000 ft., *i.e.*, it will indicate a height of 16,000 ft. when the real height is only 14,000 ft. It is always necessary therefore to "correct" the aneroid readings for temperature. The equation

$$H = \frac{273 + t}{283} \cdot h \; .$$

gives us the necessary correction. Here H is the true difference in height between any two points, t the average temperature in degrees Centrigrade between the points, and h the difference in height indicated by aneroid. It is convenient to draw a curve showing the necessary correction factors at different temperatures, some of which are given below:—

Table III.—*Aneroid Correction Factors.*

Temperature. °F.	Correction factor.	Temperature. °F.	Correction factor.
70	1.040	10	0.922
50	1.000	—10	0.833
30	0.961		

For example if a climb is made through 1,000 ft. by aneroid and the average temperature is 10° F., the actual distance in feet is only 1,000× 0.922=922 ft. The above equation is probably quite accurate enough for small differences of height—up to 1,000 ft. say—and approximately so for bigger differences. The magnitude of the correction which may be necessary shows how important it is that observations of temperature should be made during every test. For this purpose a special thermometer is attached to a strut of the machine, well away from the *fuselage*, and so clear of any warm air which may come from the engine. The French, I believe, do not measure temperature, but note the ground temperature at the start of a test, and assume a uniform fall of temperature with height. This, undoubtedly, may lead to serious errors. The change of temperature with height is usually very irregular, and only becomes fairly regular at heights well above 10,000 ft. This is shown by the following curves, which represent results taken at random from tests made at different times (Fig. 1).

Statement of the ownership, management, circulation, etc., required by the Act of Congress of August 24, 1912, of Aerial Age Weekly, published weekly, at New York, N. Y., for April 1, 1917, State of New York, County of New York. Before me, a Notary Public in and for the State and county aforesaid, personally appeared G. Douglas Wardrop, who, having been duly sworn according to law, deposes and says that he is the Business Manager of the Aerial Age Weekly, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, The Aerial Age Co., Inc., 280 Madison Avenue, New York; Editor, G. Douglas Wardrop, 280 Madison Avenue, New York; Managing Editor, G. Douglas Wardrop, 280 Madison Avenue, New York; Business Manager, G. Douglas Wardrop, 280 Madison Avenue, New York; Assistant Business Manager, G. A. Cavanagh, 280 Madison Avenue, New York.

2. That the owners are: The Aerial Age Co., Inc., 280 Madison Avenue, New York; Henry Woodhouse, 297 Madison Avenue, New York; G. Douglas Wardrop, 280 Madison Avenue, New York.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stocks, bonds, or other securities than as so stated by him.

5. That the average number of copies of each issue of this publication sold or distributed, through the mails or otherwise, to paid subscribers during the six months preceding the date shown above is (This information is required from daily publications only).

G. DOUGLAS WARDROP,
Business Manager.

Sworn to and subscribed before me this 27th day of March, 1917.

[Seal] DANIEL F. NUGENT, Notary Public.
Queens Co. 907. Certificate filed in N. Y. Co. 67. (My commission expires March 30th, 1917.)

Summer Meeting of Society of Automobile Engineers Notice Withheld Owing to Threatening International Conditions

The Society of Automobile Engineers, whose name will be changed next month to Society of Automotive Engineers, has been arranging for the most elaborate summer meeting in its history, including events and presentation of technical matter connected with aircraft, watercraft, and farm tractors, as well as motor cars. The various committees, including the Meetings Committee of which David Beecroft is chairman, and the Papers' Committee, which is conducted by H. G. McComb, have well advanced plans which can be put into final effect quickly as soon as it shall be known whether it will be possible or advisable to hold sessions of the scope intended. Meantime announcement of the time and place of the meeting is being withheld pending development of international conditions, with the thought that in the event of untoward results in this respect the society shall be as untrammeled as possible with plans interfering in any way with direct work for the Nation.

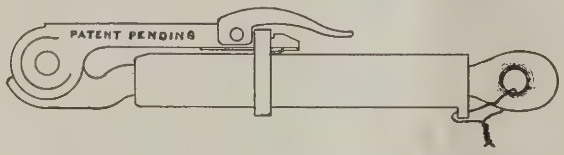
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

Burgess Training Hydroairplane

Among the many models of Airplanes, Seaplanes and Flying Boats produced by this company the new "U" type Hydroairplane meets a very pressing need—an efficient, well-balanced flying machine of conventional type and low power for militia training purposes.

The Massachusetts Naval Militia has the first one now in service.

Standard Deperdussin control in duplicate; Curtiss OXX-2 motor; simple float; light, sturdy construction; large speed range (forty to sixty-eight miles per hour); are characteristics necessary to the hard service required for training purposes.

Hydroplanes and pontoons designed and manufactured for airplanes of every type, including Curtiss, Sturtevant and other makers.

Designers and constructors for the U. S. Army and Navy and British Admiralty.

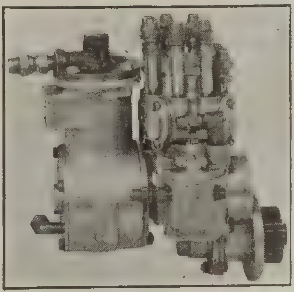
Starts High Powered Engines Cold on Low Pressure



Supplied to the U. S. Navy

THE marked efficiency of the Christensen Self Starter is perhaps best suggested by the results of a test on a Hall-Scott Motor made at the Standard Aero Mfg. plant in Plainfield, N. J. There on a tank of air of 250 pounds pressure, 28 complete starts were made without recharging the tank, and the last start was made on the low pressure of 100 pounds.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

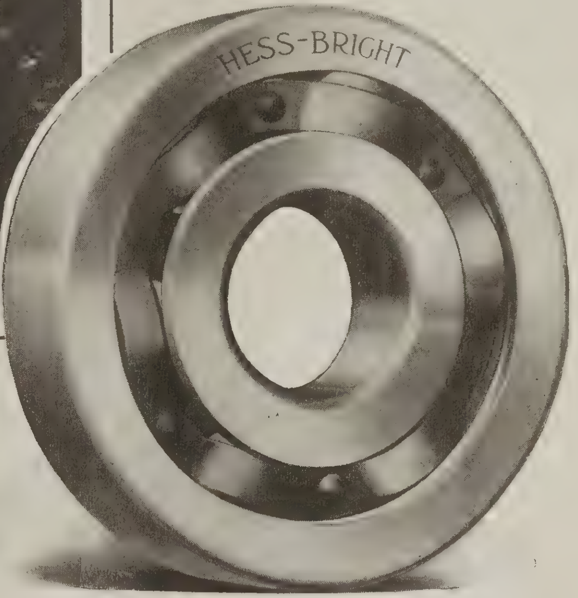
It takes KNOWLEDGE—PLUS

To produce ball bearings of HESS-BRIGHT quality requires all the knowledge that can be summoned —*plus* the desire and positive intention to make a ball bearing that shall be commensurate with the aims and ideals of an organization that stands for nothing but the best.



To produce something of inferior quality, only a little knowledge and less care, are necessary.

THE HESS-BRIGHT MANUFACTURING CO.

PHILADELPHIA, PA.

Hess-Bright's Conrad Patents are thoroughly adjudicated.

ALWAYS KEEP THE CHART IN SIGHT

Aeronautic Maps

THE Aeronautic Library has secured the exclusive agency from the Sperry Gyroscope Company for the sale of the Sperry Aeronautic Maps and is now ready to deliver maps New York-Chicago; New York-Newport News; Long Island and vicinity, etc.

Every aviator appreciates the value of an accurate map when making cross-country flights, and the Sperry Aeronautic Maps, and Sperry Map Holder, supply this necessity.

The map can be turned easily in the holder bringing constantly before the aviator a chart of the locality above which he is flying.

The equipment is light in weight and can be fixed to instrument board without interference with the other instruments.

Prices and details on application.

The Aeronautic Library, 280 Madison Avenue, New York City

AVIATION TRAINING

THE CURTISS School of Aviation will give training this winter, in Florida, to those civilians who may be accepted by the Aviation Section, U. S. A., upon their having made application for enlistment in the Aviation Reserve Corps. Applicants must be between twenty-one and twenty-seven years of age, possess good health, character and college education or equivalent. Tuition will be paid by the Government.

Curtiss J. N.
Tractor
Equipped With
Ackerman Wheels

"IT'S IN THE SPOKES"

AFTER four years' exhaustive tests, The Ackerman Wheel Company offers to aeroplane builders a wheel of special design that will solve many of the difficulties hitherto encountered.

In a series of laboratory tests (see illustrations below) the wheel was attached to a large case, into which was loaded 1,500 pounds of sand. A side thrust blow, with the wheel seven feet removed from the point of contact, was calculated to give the wheel a stress of 27,000 pounds. This was when the wheel struck the plain floor surface. To test the wheel to its maximum, two cleats of wood were nailed to the floor, four inches in advance of the striking point, and under this test four spokes of the wheel were broken. Calculation showed that the energy of the blow totalled 49,800 pounds.

A special alloy, specially treated, is used to meet all conditions that the wheel can be subjected to. The steel receives a special process in the treating, so that it will give the required resiliency, starting at the center of the curve and gradually growing stiffer and stronger both to the hub and relative to the structure of the spoke. The spokes being made on the curve, they are hung on the hinge at the rim, being a unit in the hub, allowing them to open and shut according to the load placed on the hub.

In the aeroplane wheel it is found that the hub will leave the center four inches when maximum loaded, and return to center as load is decreased, without the springs taking a set. There has never before been a wheel invented which would meet any such conditions.

These wheels can be built according to size and weight of any load from 500 pounds up to 5 tons

THREE MEDALS OF MERIT were awarded by the Aero Club of America for the following notable records:

J. FLOYD SMITH, who created three new World hydro altitude records in a Martin seaplane: January 12, 1916, with one passenger, 12,333 feet; January 11, 1916, two passengers, 9,524 feet; February 16, three passengers, 9,608 feet.

C. C. CULVER, Captain, U. S. A., for his great achievements in developing wireless equipment for sending and receiving messages from aeroplanes. All his experiments and achievements were made using a Martin Military Tractor Biplane.

A. D. SMITH, Corporal, U. S. A., who created a new hydro duration record February 19, 1916, in a Martin seaplane by remaining in the air 8 hours and 42 minutes.

Many other performances of note prove the certainty and efficiency of our designing and the superior construction of our aircraft.

SPHERICAL BALLOON FABRIC STANDARDIZED

AFTER thorough investigation of theory and practice here and in Europe, we have standardized our balloon fabrics on the bases of tensile strength, diffusion and coating.

Years of successful manufacture of these fabrics and of spherical balloons have given us the necessary verification by experience for the principles developed in our laboratories.

Our 80,000 cubic feet capacity Goodyear Spherical which won the international race at Paris in 1913 is one of a number of successes.

We have since built a number of balloons of similar type and of various sizes.

Our aeronautical experts will gladly answer inquiries regarding our fabrics and principles of balloon construction.

We manufacture Rubberized Fabric—Spherical, Kite and Dirigible Balloons of any size, every type and for any purpose—sporting, exhibition, military and naval—Aeroplane Tires, Tubes, Rubber Bumpers, Rims and other aeronautical supplies.

VOL. V NEW YORK, APRIL 16, 1917 No. 5

THE STAR SPANGLED BANNER

Oh, say, can you see, by the dawn's early light,
What so proudly we hailed at the twilight's last gleaming,
Whose broad stripes and bright stars, thro' the perilous fight,
O'er the ramparts we watch'd, were so gallantly streaming?
And the rocket's red glare, the bombs bursting in air,
Gave proof thro' the night that our flag was still there.
Oh, say, does that star-spangled banner yet wave
O'er the land of the free, and the home of the brave?

On the shore, dimly seen thro' the mists of the deep,
Where the foe's haughty host in dread silence reposes.
What is that which the breeze, o'er the towering steep,
As it fitfully blows, half conceals, half discloses?
Now it catches the gleam of the morning's first beam,
In full glory reflected, now shines on the stream;
'Tis the star-spangled banner; oh, long may it wave
O'er the land of the free, and the home of the brave.

And where is that band who so vauntingly swore,
That the havoc of war and the battle's confusion,
A home and a country should leave us no more?
Their blood has wash'd out their foul footsteps' pollution,
No refuge could save the hireling and slave
From the terror of flight or the gloom of the grave:
And the star-spangled banner in triumph doth wave
O'er the land of the free and the home of the brave.

Oh thus be it ever when freemen shall stand
Between their lov'd home and wild war's desolation;
Blest with victr'y and peace, may the heav'n-rescued land
Praise the Pow'r that hath made and preserv'd us a nation!
Then conquer we must, when our cause it is just,
And this be our motto: "In God is our trust!"
And the star-spangled banner in triumph shall wave
O'er the land of the free, and the home of the brave.

"Will you please print the Star Spangled Banner?" has been a common request since the Aero Club of America, very thoughtfully, had this stirring national song printed—and was sung by Geraldine Farrar and the 500 guests at the club's annual banquet.

We have gone to patriotic meetings and have seen enthusiastic Americans chagrined because they could not remember the words of the second and third verses of the Star Spangled Banner. They usually mean to buy a copy of the song, but always forget.

We will print the Star Spangled Banner—and, very appropriately—as the leading editorial.

CONGRESSMAN MURRAY HULBERT INTRODUCES A BILL CREATING DEPARTMENT OF AERONAUTICS

Congressman Murray Hulbert, of New York, one of the most forceful spokesmen for aerial preparedness in Congress, has introduced a bill creating a Department of Aeronautics, with a Cabinet Officer as Secretary of Aeronautics.

The Bill reads as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there be at the seat of government an executive department known as the Department of Aeronautics, and a Secretary of Aeronautics, who shall be the head thereof; and the provisions of title four of the Revised Statutes, including all amendments thereto, are hereby made applicable to said department. The Secretary of Aeronautics shall be appointed by the President, by and with the advice and consent of the Senate, at a salary of $12,000 per annum and with tenure of office like that of the heads of other executive departments; and said Secretary shall cause a seal to be made for the Department of Aeronautics of such device as the President approves, and judicial notice shall be taken of said seal.

SEC. 2. That there be in the Department of Aeronautics an Assistant Secretary of Aeronautics, to be appointed by the President, who shall receive a salary of $5,000 per annum. He shall perform such duties as are required by law and such as are prescribed by the Secretary of Aeronautics. There shall also be a chief clerk whose salary shall be $4,000 per annum, a disbursing clerk whose salary shall be $4,000 per annum, an editor whose salary shall be $4,000 per annum, and such other employees as Congress may from time to time authorize. The Auditor for the State and Other Departments shall receive and examine all accounts of salaries and incidental expenses of the office of the Secretary of Aeronautics and of all bureaus and offices under his direction and all accounts relating to all other business within the jurisdiction of the Department of Aeronautics, and shall certify the balance arising thereon to the Division of Bookkeeping and Warrants of the Treasury Department and forthwith send a copy of each such certificate to the Secretary of Aeronautics.

SEC. 3. That it shall be the province and duty of the Department of Aeronautics to supervise and promote all matters pertaining to aeronautics in its relation to the Army and Navy in times of war and peace and to endeavor to improve and develop the science of flying as may be deemed desirable in the public interest and for the purpose of extending commerce on such other ends as may be found practicable for the general betterment of the country, and said department shall collect and disseminate information relating thereto as the needs may require.

SEC. 4. That to the Department of Aeronautics are hereby transferred the aeronautic section of the Signal Corps of the Department of War and the Office of Naval Aeronautics of the Department of the Navy, and all that pertains to them are hereby transferred to the Department of Aeronautics, and they and each of them shall remain under the supervision and direction of the Secretary of Aeronautics until otherwise directed by law.

And the President is hereby authorized to transfer to the Department of Aeronautics at any time either the whole or any part, as to him may seem best, of any bureau, division, or other branch of the Government engaged in work pertaining to aeronautics.

And each and every function, authority, power, duty, and jurisdiction of whatsoever character it may be, vested at the time of any transfer aforesaid in the head of the executive department from which such bureau, division, or other branch of the Government is transferred, shall, to the extent to which such function, authority, power, duty, or jurisdiction pertains to such bureau, division, or other branch of the Government, immediately upon such transfer become vested, and hereafter remain vested, in the Secretary of Aeronautics.

All lands, buildings, furniture, apparatus, equipment, and property of whatsoever description, and all official records and papers in the custody of any executive department from which any bureau, division, or other branch of the Government is transferred as aforesaid and pertaining to the business of such transferred bureau, division, or other branch of the Government shall at the time of such transfer, or as soon thereafter as practicable and in so far as such action can be taken without hindering the work of the executive department from which such transfer is made be given over into the custody of the Department of Aeronautics. And all unexpected balances of appropriations available at the time of such transfer for the use of any such transferred bureau, division, or other branch of the Government, or which may become available thereafter, shall be and remain available in similar manner and to the same extent as if no transfer had been made.

Sec. 5. That within the Department of Aeronautics there shall be the following bureaus:

(a) Bureau of Land Operations.
(b) Bureau of Naval Operations.
(c) Bureau of Radio Communications.
(d) Bureau of Construction.
(e) Bureau of Aeronautic Research.
(f) Bureau of Motor Power.
(g) Bureau of Personnel and Accounts.

There shall be a chief of each of the above seven bureaus, to each of whom shall be paid a salary of $5,000 per annum: *Provided, however,* That any officer of the Army or Navy serving on detail in one of the aforementioned bureaus as chief, or in any other capacity, whose salary and allowances in the Army or Navy exceeds $5,000, shall be paid an additional sum, so that his salary of $5,000 per annum and the said additional sum shall equal the pay and allowances due him as an officer of the Army or Navy.

And the Secretary of Aeronautics is hereby authorized to arrange and rearrange from time to time, with the approval of the President, the functions, duties, personnel, papers, records, and property, and the work, resources, and equipment generally coming into the jurisdiction and control of the Department of Aeronautics by the operation of this Act, so as most efficiently and economically to organize and maintain the several bureaus herein named and such divisions and officers thereof as to said Secretary seems proper.

Sec. 6. That for the purpose of efficient organization at the outset of the operations of the Department of Aeronautics, officers and enlisted men of the Department of War and the Department of the Navy who are now detailed in the aeronautic service and are hereby considered as in the service of the Department of Aeronautics, and shall be detailed for duty as may be seen fit by the Secretary of Aeronautics, after consultation with the Secretary of the Navy and the Secretary of War, and for a period not to exceed four years, unless otherwise provided for by law.

Sec. 7. That the Secretary of Aeronautics may, in his discretion and with the approval of the President, appoint an advisory board of not more than seven members to confer with him upon his request, from time to time as he deems necessary, concerning the work of the Department of Aeronautics. The members of said board shall be selected because of their special knowledge of matters relating to aeronautics and flying, and each shall hold office for a term of seven years, or until his successor is appointed, except that the appointments first made, and appointments thereafter made to fill unexpired terms and tearms of members who have held over beyond the periods of their original appointments, shall be made so that no more than one member shall retire during any one fiscal year. No member of any such advisory board shall receive any compensation for his services, but each shall be paid all actual expenses necessarily incurred in the discharge of his duties. They shall automatically become additional members of the National Advisory Committee for Aeronautics, created by an Act entitled, "An Act making appropriations for the naval service for the fiscal year ending June thirtieth, nineteen hundred and sixteen," approved March third, nineteen hundred and fifteen.

Sec. 8. That the Secretary of Aeronautics shall annually submit to Congress a report in writing showing the operations of the Department of Aeronautics during the last preceding fiscal year, which report shall give an account of all moneys received and all moneys disbursed on account of such operations. He shall make such other reports from time to time as may be required by the President or by either House of Congress and such as are in his judgment necessary or expedient.

Sec. 9. That $1,000,000 be, and the same are hereby, appropriated to carry into effect the provisions of this Act, out of any money in the Treasury not otherwise appropriated, in addition to all continuing funds and all other sums now available for Army or Navy aeronautics, or which may be made available for aeronautics in any manner whatsoever by the present session of Congress.

Sec. 10. That all Acts and parts of Acts contrary to the provisions of this Act or inconsistent therewith be, and the same are hereby, repealed.

Sec. 11. That this Act shall take effect on and after July first, nineteen hundred and seventeen.

The Aero Club of America has been urging the establishment of a Department of Aeronautics for the past two years, so as to bring about a closer co-operation between the Army and Naval Air Services, and the co-ordination of military and civilian resources. Two years ago, before the Club declared itself in favor of the Department of Aeronautics, Mr. Alan R. Hawley, President of the Club, was mentioned as the logical Secretary of Aeronautics, to be a member of the President's Cabinet. But Mr. Hawley stated then that he would not under any consideration accept an office of any kind, feeling that he could do just as much, perhaps more, work for the country as President of the Aero Club of America, or as a worker for the upbuilding of our national defenses. Mr. Hawley put himself on record in Congress and with the press at the time as declining to accept any office. As his name has been mentioned during the past two weeks as the logical Secretary of Aeronautics, Mr. Hawley has authorized the statement that he cannot consider, and will not accept any official position—but will be glad to continue to give his entire time, energies and resources to the upbuilding of the nations aerial defenses and other national work.

CONSTRUCTIVE PATRIOTISM

TO meet the serious need for a large number of aviators in connection with the upbuilding of our aerial defenses, steps are being taken to establish a huge aviation training camp for college men.

Messrs. Henry P. Davison, of J. P. Morgan & Co., Lewis Thompson, another wealthy New Yorker, and F. Trubee Davison, who organized Volunteer Aerial Coast Patrol Unit No. 1, are developing a plan, in co-operation with the naval authorities, the National Aerial Coast Patrol Commission, of which Admiral Peary is the Chairman, and the Aero Club of America.

The decision to establish this huge training camp, which will easily accomodate 100 students, was reached following the consideration of the need for aviators for the Aerial Coast Patrol of the Second and Third Naval Districts, which brought out the fact that not less than 3,000 aviators, 50 dirigibles balloon pilots, and 100 observation balloon operators are needed for the defense of these two naval districts.

The duties of the Aerial Coast Patrol are to be as follows:

(1) To locate and assist destroyers, trawlers and submarine chasers in capturing or destroying hostile submarines.

(2) To locate submerged mines and assist trawlers in destroying mines.

(3) Searching the coast for submarine bases.

(4) To convoy troop and merchant ships and coastwise trips.

(5) To patrol the coasts, holding up and inspecting doubtful ships and convoying them to examining stations.

(6) Attacking hostile ships and submarines that may show up near the coasts, with torpedoes, bombs and guns.

(7) Protecting ships at sea and in ports against attack from hostile submarines and battleships.

(8) Communicating to incoming ships information regarding the location of mines, submarines and the courses to follow to avoid mistakes and confusion.

(9) Serving as the "eyes" of mine planters, minimizing the time required for mine planting.

(10) Defending and protecting naval bases and stations from naval and aerial attacks.

It was after considering the vital need of aviators for the Aerial Coast Patrol and the realization of the fact that in case of war the fifty or so U. S. naval aviators available would be merely a drop in the bucket, that made the Davisons decide last summer to organize a unit of the Aerial Coast patrol. That unit was formed on July 7th last, and the twelve members trained continuously throughout the summer at Port Washington, and during the fall at New London, in co-operation with the officers of the Navy Yard there. The unit also participated in the Mosquito Fleet maneouvers held at Gravesend Bay from September 5th to 12th, during which they gave remarkable demonstrations of their efficiency and of the value of the Aerial Coast Patrol as a whole.

MEMORIAL—TO PETER CARL (TEX.) MILLMAN

Time in its tireless flight, has brought us again to the full realization that the Grim Reaper is ever amongst us. Life at best is frail and may be taken from us or blown out in a brief second as a candle in a gale.

Little we thought that you, "Tex," our Chief Instructor, congenial associate, co-worker and friend, would be, could be taken away to the Great Beyond after one week of illness.

We hoped on, prayed on for you while you were away, and now that you are gone, we will always remember you as a most willing and earnest worker of the Flying Service.

Your star will shine in the firmament and your brother pilots will look for you there. We cannot say, we will not say, that you are gone, you are just away.

Years may roll on with their sunshine and shadows, laughter and tears, sowing and reaping, cradle songs and funeral hymns, but your memory will ever live with us.

To those near and dear to you, we, the Officers, Instructors, Soldiers and Civilian Employees of the Aviation Station, at Mineola, extend our heartfelt sympathy, and feel deeply for them in their bereavement.

At the time of Germany's declaration of her intention to prosecute a campaign of ruthless U-boat warfare, the Davisons and all the members and officials of the Aerial Coast Patrol Commission and the Aero Club of America, realized that this policy might mean the involving of this country in war, and that in such a case there would be needed many aviators for coast patrol duties. The 29 members of Volunteer Aerial Coast Patrol Unit No. 1 made plans to leave Yale University and go to Florida to continue their training, so as to be available and to be thoroughly trained in case of emergency.

The report that the Unit was to go to Florida for training stirred up tremendous interest among the students at Yale, Princeton, Columbia, Harvard and other Universities, and as a result, the Unit was flooded with hundreds of applications from college men anxious to join the Unit and to form other units.

Arrangements were made for Unit No. 1 to take on 2 additional members, making 29 members in all, to the aviation training camp established by Mr. Rodman Wanamaker, at West Palm Beach. Mr. Lewis S. Thompson agreed to assist the Davisons in this patriotic work, and as Mr. H. P. Davison, Sr., could not himself go to Florida, Mr. Thompson took charge of the general supervision of the Unit. Messrs. W. D. Gash, who is Mr. Rodman Wanamker's right hand man, Stuart McDonald, manager of the Aviation School, and David McCulloh, the chief pilot of Mr. Wanamaker's school, are co-operating with and assisting Mr. Thompson. As the demand for training was so large, and in view of the approaching emergency, it was decided to give the Unit a military formation, which was done. The Camp at West Palm Beach is running on a military basis, the members of the Unit getting training in discipline, aerial gunnery, wireless, and general aerial coast patrol work, as well as in the operation of aeroplanes.

Mr. Henry Woodhouse, a member of the Board of Governors of the Aero Club of America has presented to the Unit, through the Aero Club of America, a Lewis aeroplane gun, with 2,000 rounds of .333 ammunition, to enable the Unit to get practical experience with an up-to-date aeroplane gun.

The plan was to have Unit No. 1 train at West Palm Beach until the weather permitted establishing a camp on Long Island. While the plans for this camp were being considered, the applications for training from college men became so numerous that the patriotic people who are contributing towards the training and equipping of aerial Coast Patrol Unit No. 1 decided to extend their support so as to increase the number of men to be trained to 100.

The plan was submitted to the Navy Department, and the authorities have given valuable suggestions, and are co-operating in carrying it out. This camp is to be established on Long Island, near New York, and several cities are under consideration.

The 29 men now under training at West Palm Peach represent some of the most prominent families in the United States, and are as follows: F. Trubee Davison and Henry P. Davidson, Jr., sons of Henry P. Davison, member of the firm of J. P. Morgan & Co.; Robert A. Lovett, son of Judge Lovett, Chairman of the Executive Committee of the Union Pacific Railroad; Albert J. Ditman, Charles Wiman, Artemus L. Gates, Allan Ames, John V. Farwell, John Vorys, Earl Gould, Wellesly Laud-Brown, Reginald G. Coombe, Oliver B. James, G. Franklin Lawrence, William Rockefeller, Frederick Beach, Kenneth Smith, Kenneth McKleisch, Curtis Read, Barlow Read, David Ingallis, A. D. Sturtevant, William Thompson, Frank Lynch, Graham Brush, Henry Landon, Samuel S. Walker, Charles Stewart, Archie McIlwaine.

At first, it was thought that there would be difficulty in getting the aeroplanes needed for the training camp, but the investigation of the National Advisory Committee on Aeronautic showed that the aeroplane manufacturers are ready to extend their facilities so as to supply 5,000 aeroplanes this year, provided that orders for continuous deliveries are given. Heretofore the Government has only placed orders for immediate deliveries, and the manufacturers having nothing to look forward to, could not extend their facilities to create greater sources of supply, but now that the National Advisory Committee on Aeronautics has decided to have the Army and Navy place large orders for continuous deliveries, extending over two or three years, the manufacturers are going ahead developing their facilities and purchasing materials needed in the manufacture of aeroplanes and motors, and will be able to begin to make substantial deliveries in a very short period of time.

National Advisory Committee on Aeronautics Prompt in Taking Steps for Developing Our Aerial Defenses

THE patriotic people who, for the past two years, have contributed their efforts—and considerable money—to developing our aerial defenses will be gratified to learn that the National Advisory Committee on Aeronautics has been prompt in taking steps for developing our aerial defenses.

To-day is the day of National appreciation for the energetic efforts of those who worked untiringly in the past three years to develop our defenses and who, by personal contributions and sacrifices, sought to prepare the nation for the present emergency. And it is also the day of appreciation for the efforts of those who, in the past two weeks, have been working preparing plans which are to give the United States an adequate air service.

Dr. Charles D. Walcott, the chairman of the Executive Committee of the National Advisory Committee on Aeronautics, is to be congratulated upon the work of his committee.

It is indeed gratifying to be able to tell the hundreds of anxious patriots who inquire at the Aero Club of America, at our offices, and at other patriotic organizations, whether substantial steps are taken to prepare this country that we are preparing, at last!

These patriots are too patriotic to want to know in details; they appreciate that public interest demands that any facts about our preparedness which may help the enemy must be withheld from publication, and accept the statements of the leaders of the national defense moevment regarding the status of things.

Let us hope that the plan to train 2,500 aviators by the end of the year will be put into effect, so that every minute of flying weather can be used to train aviators for national defense!

America Awakes

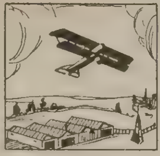
America has waked at last.
The fearless Eagle screams his rage.
Insult and Murder of the past
Have loosed the barriers of his cage,
Where Liberty has sat in tears,
In sorrow bound these awful years;
In hope the bitter cup might pass,
Alas! that hope is vain, Alas!

But, since it has to be, my friends,
Each man give up his selfish ends
And aught that love of country bars,
Unfurl the glorious "stripes and stars."
Though deep in slumber wrapped so long,
When once aroused, like giant strong,
America will rise in might
Prepare and join in any fight.

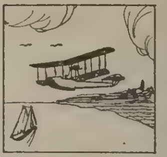
Protecting helpless mortals riven,
Whose only crime is they have striven
To carry out the world's decree,
Based on a great humanity.
America has raised her head;
The spirit that seemed almost dead
Has burst into celestial fire
Her soul filled with a righteous ire.

Thou enemy of God, beware!
Thou ruthless vandal, have a care.
From east to west and back again,
As grows the stream with winter rain,
The soul of Washington revives,
And Lincoln's life goes through our lives.
The world cries out with clarion voice,
"America's awake! Rejoice!"

George L. Upshur.



THE NEWS OF THE WEEK



N. Y. City to Present Aviation Field

New York City.—In response to a request from the Army and Navy Departments, the city will lease to the Government at an annual rental of $1 a year sixty acres of city land within the limits of Rockaway Park for an aviation base. The Mayor has called a special meeting of the Sinking Fund Commission and the request will be formally granted.

The request for the land was made in the following letter to the Mayor from the Secretaries of the Army and Navy Departments:

"The present emergency demands immediate establishment of this station for the protection of New York City and the patrol of its outside waters. It is therefore requested that you take such action as will enable the two Departments to have the earliest possible use of the site."

Aerial Paul Revere

New York City.—Designating Thursday, April 19, the anniversary of the battle of Lexington, as a national recruiting day, Alexander J. Hemphill, chairman of the committee on recruiting of the Mayor's defense committee, has telegraphed the Mayors of 531 cities asking their co-operation in bringing the Army and Navy up to war strength.

As part of the program the committee has arranged to duplicate Paul Revere's ride, to have the poem of Paul Revere recited in all public schools, theatres and churches on that day and shown on the screens in all moving picture houses, and to have a modern Paul Revere spread the alarm through old Middlesex County by aeroplane while church bells toll and factory whistles scream.

Aviation Recruiting Fast

Mineola.—Reports from the Signal Corps Aviation School at Mineola, Long Island, and other aerial training stations prove that the declaration of war has had an electric effect on the young men who are patriotic and wish to serve the colors. Heretofore there has never been a great number of applicants for aviation training, but if the record for applicants established last week keeps up it will be necessary for the Army and Navy officials to establish new schools. Heretofore the young man who was willing to do his share for the country chose some line other than flying. The aviation corps was looked upon as a body of men who did not care what became of themselves. Recent publicity has made an impression, however, and this, coupled with the fact that the greatest need of the hour is for aviators and flying machines to be used for coast patrol service, has caused a change. There is no other line of service that presents the opportunity for promotion as does the aerial branch. It affords an opportunity for the young American to do things of real valor, and, having done them, he may be sure of instant recognition.

American Philosophical Society Holds Aeronautic Session

The American Philosophical Society devoted the concluding afternoon of its series of conferences to the subject of aeronautics, many phases of which were covered by experts of prominence. The following was the program:

Dynamical Aspects: By Arthur Gordon Webster, Ph.D., LL.D., Member of Naval Advisory Board.

Physical Aspects: By Brigadier-General George O. Squier, Ph.D., Chief of Signal Corps, U. S. Army. (Introduced by Dr. Keen.)

Mechanical Aspects: By William Frederick Durand, Ph.D., Chairman of National Advisory Committee for Aeronautics. (Introduced by Dr. Walcott.)

Aerology in Aid of Aeronautics: By Charles F. Marvin, M.E., Chief of the United States Weather Bureau.

Mathematical Aspects: By Edwin Bidwell Wilson, Ph.D., Professor of Mathematics, Massachusetts Institute of Technology. (Introduced by Dr. E. W. Brown.)

Engineering Aspects: By Jerome C. Hunsaker, Eng. D., Assistant Naval Constructor, U. S. Navy. (Introduced by Dr. Bauer.)

Excellent Hall-Scott Record

A Hall-Scott A-70 90 h.p. four-cylinder engine, in a Martin model T. T. aeroplane at the Army School at San Diego, Cal., recently completed 102 hours and 39 minutes without being overhauled or taken out of the aeroplane, according to L. S. Scott, secretary of the Hall-Scott Motor Car Company.

Fowler to Form New Company

Robert Fowler, one of the organizers of the L. W. F. Engineering Co., is at the present time in California laying the foundations for a new aeroplane company, which will probably be located at Vallejo, Cal.

Yale Aviation Students Visit Curtiss Factory

Sixty Yale Senior Engineering students in charge of Prof. J. W. Roe, Prof. H. L. Seward, Mr. E. O. Waters and Mr. E. M. Wilcox, recently came all the way from New Haven to Buffalo to visit the Curtiss aeroplane factory and see applied in actual practice the theories which they had been studying.

At both Yale and Harvard large bodies of students have already signified their intention of entering the aviation corps, and several Harvard and Yale men are already in the training schools. Princeton is laying out a field which, it is expected, will soon be in active operation.

University of Michigan and the University of Illinois and many of the other Western colleges are equally interested, and it is said that over 5,000 requests for aviation training have been received by the Curtiss Company alone within the last two weeks.

Franklin K. Lane, Jr., Soon To Be Pilot

Franklin K. Lane, jr., son of the Secretary of the Interior in President Wilson's Cabinet, will soon finish his course of instruction in flying at the Government Aviation School at Newport News.

Ruth Law Back

Miss Ruth Law, the holder of the American Distance Record, returned from France last week, after spending several months in England and France, observing the latest methods of aerial warfare.

"I am at the service of my country for flying duty at any moment I may be called upon," she said.

"I am willing to fly a fast little scout machines alone, travelling 130 or 150 miles an hour, or I'll drive a heavier machine carrying a gun and gunner and go into actual battle with the enemy," added the diminutive holder of the Chicago-New York flight record. "That's what I'd like to do more than anything—get right into the fight.

"The only request I shall make of the Government when I offer my services formally, which will be in a day or so, is that I be sent to the front, wherever it is. Above all things, I'd like to go to the front in France, if America sends any soldiers over there.

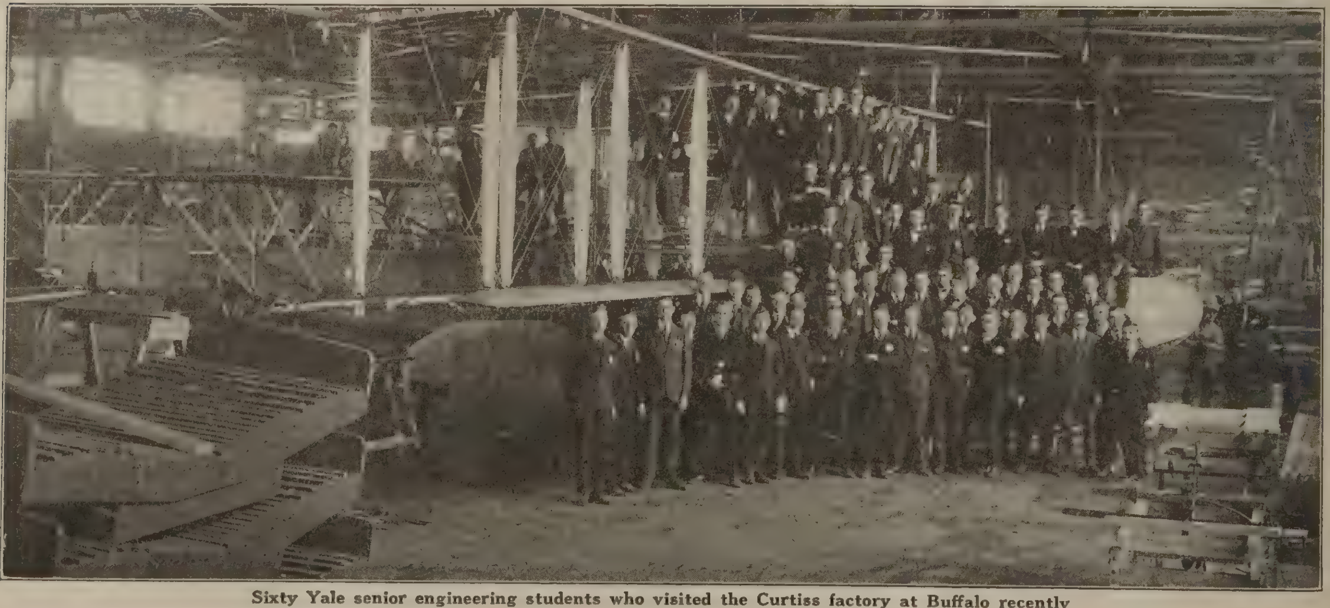
"If we have a woman Congressman, why can't we have a woman fighting aviator?" she demanded.

Miss Law tried to get to the fighting front, but was permitted no further than Compiegne, close to where the Germans were turned away from their march toward Paris early in the war.

"I met all the boys of the Lafayette Escadrille—the American flying group," she said, "and I had the privilege of chatting with the greatest fighting flyer of all, Lieut. Guynemer, who has shot down more than thirty flyers. He gave me a ring fashioned from the button of a German airman's coat."

"I saw a wonderful new bit of trick flying at Le Bourget," she went on. "It is a stunt called 'le vrille' (the gimlet). While the machine is on a level, the head stands still and then the tail whirls around and around. It is done by jamming the rudders. But, with all the fancy flying I saw, I still believe the best trick aviator I ever beheld was Lincoln Beachey, our own Yankee boy."

Miss Law brought back with her a French trench dog called Poilu, who saw much actual fighting and was wounded several times. He wears a miniature steel helmet. He had to go into quarantine because of the regulations regarding the importation of animals.



Sixty Yale senior engineering students who visited the Curtiss factory at Buffalo recently

Aviation Day at San Francisco

San Francisco: Preservation of the Column of Progress as a national memorial to aviators was taken over last night at the Palace Hotel by the Pacific Aero Club, and April 22 set as aviation day. A great public celebration will be held on that date to raise money to make permanent the famous monument on the Marina.

The committee in charge consists of J. C. Irvine, president of the Pacific Aero Club; Roy Francis, Lyman Doty and Frank Bryant, aviators, and E. T. McGettigan of Redwood City.

May Establish Aviation Co. in Arkansas

Little Rock, Ark.: Governor Brough of Arkansas has appointed Major W. H. Abington, of Beebe, surgeon of the First Infantry, as president; Capt. Berne F. Jungkind, of Beebe, surgeon of the First Infantry, and Capt. Glen M. Holmes, of Little Rock, assistant surgeon of the Second Infantry, as recorder, to constitute a board to examine applicants for the aviation service of the Arkansas National Guard.

Only members of the Guard will be eligible for the tests. Its purpose is to secure officers and men to take six months' training in some of the Government aviation schools. If a sufficient number can stand the tests and receive their Government licenses as pilots it is possible that an aviation corps may be authorized in Arkansas.

Candidates who pass the examination and are assigned to Government schools will be required to pay their own transportation and expenses to and from the schools, but will be on the pay of their rank while in attendance.

Examination for commissions in the Guard will be held at the Military Department next month.

Georgia Technology to Have Aviation School

Atlanta, Ga.—The trustees of the Georgia School of Technology, one of the largest and best known engineering schools in the South, have offered the school to the Government as a military training center for officers in the engineering reserve corps. The entire Tech. plant, with the full corps of instructors, is included in the offer.

In addition, it is proposed to establish an aviation school in connection with the school. It is probable that the flying field will be at Fort McPherson, while the technical instruction necessary to airmen will be given at the Tech. plant. Representatives of the institution have recently been in conference with General George O. Squier, chief signal officer of the United States Army, and Major General Leonard Wood. It is now believed that the Government will avail themselves of the offer within a few days. General Wood was at one time director of athletics at Georgia Tech., and is particularly interested in its present patriotism. The entire senior class, about a hundred men, has expressed its readiness to enter the army engineering corps.

Illinois Students Form Aero Corps

Champaign, Ill.—A students' aviation corps is to be the next addition to the military units of the University of Illinois. College soldiers who have aspirations to fly sent Prof. E. N. Fales, assistant professor mechanical engineering, to Washington to confer with army officers, and the new corps is the result.

Present plans include arrangements for actual flying training. After the student has become proficent and completes his course, he may become a lieutenant in the officers' reserve corps. The course to be arranged will include technical laboratory work and testing of aeronautic engines and propellers. So enthusiastic are the students over the new plan that a mass meeting is to be held soon at which volunteers for the new corps will be called for.

Physical Requirements of Aviators

"The advent of the aeroplane in modern military equipment has made it necessary to modify to some extent the method of physical examination of applicants," writes Dr. Charles P. Small in the Journal of the American Medical Association. "Because of the unusual and, until within a few years, the absolutely unknown conditions which the aviator must encounter, there must be a special standard of physical fitness, quite different in some respects from that required of men in other branches of military service. In time of peace the physical standard in all branches of the service should be maintained at the highest possible point. In time of war, when the need for all available fighting forces is urgent, the physical requirements of recruits might have to be considerably lowered. To lower the standard required of aviators, however, even in time of war, would be to incur the danger of most serious risks." He summarizes the optical requirements of a successful applicant for Army aviation service as: Uncorrected vision of 20/20 in each eye; binocular vision; absence of nystagmus; normal muscle balance and competent ocular muscles; normal pupillary reaction and no pupil irregularities when dilated; normal media and fundi; normal visual fields, by perimetric examination; normal color sense.

Princess Indita Rivola Hinodi Bennessee Meaning preparatory to flight in a Martin tractor at San Diego

Navy Buys Lewis Guns

As the result of a test held by the United States Marine Corps, at Winthrop, Md., on the corps' rifle range, Chief of the Bureau of Ordnance of the U. S. Navy Department, Admiral Ralph Earle, has placed an order for 2,000 Lewis machine guns, chambered for United States ammunition, with the Savage Arms Co., of Utica.

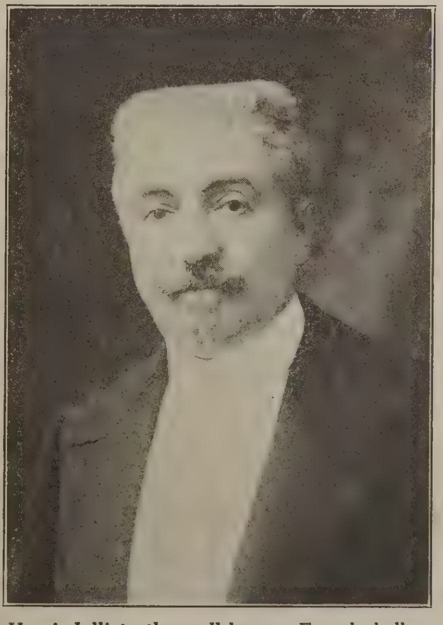
L. W. F. Co. Expands Plant

The L. W. F. Engineering Co., of College Point, has found it necessary to expand their factory space, and a new building is in course of erection. The plant is under guard of militiamen.

Searchlights Guard Aviation Field

Mineola, L. I.—As soon as news of the Belmont Park fire reached the military aviation camp here extra precautions were taken to guard the camp. All passes were revoked.

A half dozen searchlights have been installed and they will be played all over the grounds throughout the night. They will be placed on elevated positions which command every section of the grounds and hangars and be kept constantly in motion, making it impossible for any one to approach without being seen.



Henri Julliot, the well-known French balloon expert, who is in charge of the B. F. Goodrich aeronautical department

Army and Navy News

The fact that private insurance companies require aviators to surrender their policies when they begin making flights may compel the Government to enter the insurance business to a certain degree. Next to the lack of machines, it is understood that this question of inadequate protection for the dependents of the flyer is the biggest obstacle met by the Army and Navy officers who are working to complete the Aviation Corps of the Services. The lack of machines is expected to be remedied as soon as the plans discussed at recent conferences have been put into operation.

Plans for the organization of an aviation company of marines have been completed and now only wait the training of the personnel, a portion of which is already at the naval aeronautical station at Pensacola, Fla. With the equipment which has been gathered at the Philadelphia advance base depot is included a three-ton truck of the "F. W. D." type, equipped with a complete machine shop for making repairs to aeroplanes. This truck is similar to that adopted by the Signal Corps and Quartermasters Corps for the same work. Tentative proposals for two more of the same type have been asked from the concern which makes them for the marines' aviation company.

Capt. Reynold C. Bolling, S.O.R.C., in civil life a solicitor for the U. S. Steel Company, has offered to recruit and equip the personnel for one complete air squadron to be attached to the Signal Corps of the Army. Capt. Bolling's plans have progressed to the point where the War Department has opened negotiations for a lease of a suitable field outside New York to be used as a training ground for the squadron. The aeroplanes and other equipment will be furnished by the Government if the offer is accepted, this being necessary in view of the promise voluntarily made by each of the twelve firms making aeroplanes to accept no private contracts until the wants of the War Department had been met.

Lieut. Harold S. Martin, Signal Corps, U. S. A., who has been taking a special course in aeronautical engineering at the Massachusetts Institute of Technology, has been ordered to the aviation school at Mineola, L. I. Capt. Charles DeF. Chandler, U. S. A., who has been in charge of the Army Balloon School at Fort Omaha Neb., will be ordered to Washington soon. Captain Chandler's experience and training as a balloon expert will be utilized at headquarters.

Capt. Edgar S. Gorrell, junior military aviator, S. C., from duty at the Massachusetts Institute of Technology, Cambridge, Mass., to Washington and report in person to Chief Signal Officer of the Army for duty in his office. (March 30, War D.)

Capt. Harold S. Martin, S. C., from duty at the Massachusetts Institute of Technology, Boston, Mass., and to Mineola, Long Island, N. Y., Aviation Station, for duty. (March 29, War D.)

First Lieut. Harold M. Gallop, Aviation Section, S. O. R. C., to active duty at Fort Sam Houston, Texas, with 3d Aero Squadron for duty. (March 30, War D.)

First Lieut. William G. Schauffler, Jr., Aviation Section, S. O. R. C., is assigned to active duty and will proceed to Fort Sam Houston for duty with 3d Aero Squadron. (April 2, War D.)

Sergt. Harry M. McCuiston, S. E. R. C., from active duty at Curtiss Aviation School, Newport News, Va., April 5, to home. (April 3, War D.)

Sergts. Chester E. Wright and Howard C. Smith, S. E. R. C., Fort Monroe, Va., to active duty at Curtiss Aviation School, Newport News, Va., April 3. (April 3, War D.)

Sergt. Roderick H. Jones, S. E. R. C., from active duty at Curtiss Aviation School, Newport News, Va., April 5, to home. (April 3, War D.)

Sergt. William N. De Wald, S. E. R. C., Fort Slocum, N. Y., to active duty at the Curtiss Aviation School, Miami, Fla., April 1, 1917. (March 28, War D.)

Sergts. Bernard A. Law and Alfred R. Metzgar, Jr., S. E. R. C., now at Fort Monroe, Va., are assigned to active duty in Aviation Section of Signal Enlisted Reserve Corps, with station at the Curtiss Aviation School, Newport News, Va., April 1. (March 29, War D.)

Sergts. Rutledge B. Barry and Wallace D. Culbertson, S. E. R. C., now at Key West Barracks, Fla., are assigned to active duty in the Aviation Section of the S. E. R. C., with station at the Curtiss Aviation School, Miami, Fla., to take effect April 1, 1917. (March 29, War D.)

Sergt. John M. Foote, S. E. R. C., Memphis, Tenn., to active duty, with station at the Signal Corps Aviation School, Memphis, April 1. (March 30, War D.)

Sergt. John G. Colgan, S. E. R. C., from active duty at Curtiss Aviation School, Newport News, Va., to home. (March 31, War D.)

Summer Meeting of Automotive Engineers

The annual Summer Meeting of the Society of Automotive Engineers will be held Tuesday, Wednesday, Thursday and Friday, the last week in June, at Ottawa Beach Hotel on Lake Michigan. Ottawa Beach is located on the east shore of Lake Michigan approximately 100 miles across the lake from Chicago.

For the last three years the Society of Automobile Engineers has held its summer convention on a steamboat on Lake Huron, but not many months ago the council of the society decided that owing to its amalgamating with aviation engineers, farm tractor engineers, motor boat engineers, etc., that the convention this year should be held at some point where it would be possible to have demonstrations of aeroplanes and hydroplanes. Ottawa Beach is ideally suited for such in that it is at a point where Black Lake connects through a narrow channel with Lake Michigan. Black Lake is a small body of water six miles in diameter and ideal for hydroplane work. It is also ideal for motor boat work.

It may be possible to have an aeroplane or hydroplane daily mail service from Chicago to Ottawa Beach during the four days of the convention.

Another reason for holding the convention at some such exclusive hotel center as Ottawa Beach is that it will permit of several divisions of the society meeting at one time, which was not possible on the steamboat. For example on one day it may be possible that aeroplane engineers will be discussing some feature of plane construction or trussing; farm tractor engineers may be discussing wheels, speeds, etc.; motor boat engineers may be discussing standardizing boat dimensions, etc.; and automobile and motor boat engineers discussing questions local to their vehicles. This programme can be perfectly carried out at this beach.

On other days when questions of motor, balance, ignition, lubrication, testing, etc., are under consideration, all departments can meet in one group.

It is possible that the forenoons will be given over to professional work and the evenings to recreation. Each afternoon there will be some short illustrated engineering lecture and there will be many special moving picture films of an engineering nature.

Memorial Services for J. R. McConnell

Carthage, N C.—A memorial service was held in the court-house, April 1st, for the late Sargeant McConnell, of the American Flying Corps, with the French Army. Messages were read from many persons of prominence, including the Governor of North Carolina, the French Ambassador, and the parents of Victor Chapman, and Kiffin Rockwell, aviators who also gave up their lives for France.

Alexander Graham Bell Honored

Dr. Alexander Graham Bell, inventor of the telephone, and a great friend of aviation, was presented with the Civic Forum Medal of Honor for Distinguished Public Service in New York City on March 22. Among the prominent speakers of the evening was Rear-Admiral Robert E. Peary.

Will Build Aeroplanes on the Cape

Portland, Me.—An aeroplane factory of large proportions is to be erected within a few weeks in the shipyards of Captain Philip H. Doyen on Cottage Road and arrangements for the erection of the structure are well under way at the present time. The output will be delivered to the Italian Government.

This new industry will mean the employment of a large amount of help and the work of manufacturing the air craft in the proposed new factory will mean a decided stimulus to South Portland business.

Personal Pars

Mr. Arthur M. Johnson, of 308 Renova Street, Hazelwood, Pa., has invented a type of aeroplane with which he expects to beat all speed records, and in the large size, carry 22 men, and be a terror in air battles.

An airship invented by Charles Hunsicker, 220 Northwestern Avenue, Dayton, Ohio, is exciting considerable interest among those who have seen the machine and had its principles explained. Those to whom the inventor has exhibited his work have pronounced it practical and Mr. Hunsicker is planning soon to place it before the Greater Dayton Association Inventions Committee for approval and financial assistance.

Westfield, N. J.—Russell G. Clotworthy, aged 18 years, and Francis McAllister, aged 19 years, have enlisted in the Aviation Corps and are now at Fort Slocum, where they will receive training before starting for the West. The two boys quietly planned to enter the service of Uncle Sam as birdmen, and when they left their home for business one morning recently they failed to return at night, but instead left a note on Mr. McAllister's desk in New York, in which they said they had enlisted.

Irah D. Spaulding, of Brattleboro, Vt., has been appointed First Lieutenant in the United States Aviation Corps. He has been assigned to Fort Wood, N. Y., for a short course before going to San Diego, Cal., as instructor in the Curtiss School. He won his license at the Curtiss School in 1912 at the age of 19, being at that time the youngest licensed aviator in the United States. He has made several flights in this locality. Three years ago he married Miss Louise Cherrie, of Newfane, daughter of Prof. George K. Cherrie, the naturalist, who accompanied Col. Roosevelt on his South American trip of exploration.

A unique test was made recently with a Martin tractor, when an Indian motorcycle was lashed to the fusilage and the cycle and its rider successfully transported through the air. The test was arranged by Glenn L. Martin to demonstrate a new phase of the aeroplane's military usefulness

Curtiss Plant to Run 7 Days a Week

Albany, N. Y.—The State Industrial Commission has given permission to the Curtiss Aeroplane Company, of Buffalo, to operate its plant continuously for seven days a week, exempting the company from the provisions of the "one day of rest in seven" law during the present war emergency.

"The company," says a statement issued by the commission, "sets forth that the United States Government was insistent upon a large number of aeroplanes as soon as possible and that this could not be done unless the plant was operated continuously."

Members of the commission declared that they would do everything in their power to facilitate the speedy manufacture and delivery of munitions, aeroplanes, submarines and all other supplies needed by the Government "in the war emergency now confronting the country."

They, however, are opposed to the Johnson bill, directing that the provisions of the labor law, limiting the hours of labor of minors and women, shall not apply to the employment of persons over sixteen years of age in the manufacture of military supplies for the United States or any State. On the advice of the Industrial Commission the measure has been killed by the Assembly Labor and Industries Committee. It is held that to enact such a provision would break down the safeguards in the labor law and the commission has authority now to make proper variations.

Rhode Island Aviation Corps Needs More Men

Providence, R. I.—Need of men in a newly organized section of the aeroplane division of the Rhode Island Naval Militia has been announced by officers of this unit of America's defenders and that applicants for admission to the service will be received at the State Armory. It is explained that the physical examination is rigid but that the opportunities are excellent. Applicants must be 18 years or over and American citizens. One division of this service has already been filled and the new one, it is expected, will soon have its completement.

Several men have already enlisted for air service for three years as national naval volunteers, but there is yet room for about 16 more men, needed to complete the division, which at war strength, should total 56 men and officers.

At the present time two officers and four men of the division are in Pensacola, Fla., receiving three months instruction' in the operation of aeroplanes. The same number have just completed a similar tour of service.

French May Send Aviation Instructors

Paris.—Plans are being made with a view to offering to send a French aero mission to the United States when hostilities between that country and Germany begin. It will consist of a number of superior pilots, observers and gunners to serve as instructors in the American army and navy. As in the case of other French air missions to the allied nations, volunteers will be called for, but preference will be given to American or English speaking pilots of a certain amount of experience and proved ability.

Several of the crack French airmen have already applied to the director of aviation for service on this mission, and undoubtedly there will be many more when the time comes.

Army and Navy News

Following is a list of the personnel under training at the Memphis Government Aviation Station:

Capt. Joseph C. Morrow, Signal Corps, Officer in Charge.

Capt. Arthur R. Christie, Officer in Charge of Training.

First Lieut. William R. Van Sant, Supply Officer.

First Lieut. William W. Spain, South Dakota National Guard (Student).

Albert C. Adams, Frank W. Alsip, Charles W. Browne, George F. Fisher, John M. Foot, Austin E. Gibson, Reuben H. Harper, Samuel A. Herrick, Percy N. Hollowell, Eugene B. Jones, George J. Kinberg, George E. Knight, Earl E. Leonard, Donald Lyle, Alexander McLeod, Fletcher L. McCordic, Arthur Mitchell, Andrew C. Ortmayer, Harry W. Powers, Carlyle Rhodes, Harold M. Sanford, George J. Sawyer, Rudolph W. Schroeder, Carlos B. Stevens, Thorn C. Taylor, William A. Thompson, Joseph Van Walchshauser, Orrin E. Wolf.

Sergeants Michael L. Gerlowski, Grant C. Melvin and Victor J. Picard; selected cilivian mechanicians, Robert H. Houser, Joseph Pallisard, Julian Sykes and Wilfred G. Threader.

Charles Chester, Sergeant first class. Sergeant Roy R. Showalter and William F. Jones, private first class.

There are nine aeroplanes in commission at the station.

Aeronautic Plans of the B. F. Goodrich Co.

Henri Julliot, the prominent French engineer and builder of dirigibles, although he arrived in this country but several weeks ago, is already deep in the work of constructing the two huge Blimp type non-rigid diriigble balloons which are being built for the Government by The B. F. Goodrich Rubber Company, where he has accepted the commission as chief of the Goodrich Aeronautical Division.

It was not until two years ago, following a visit to the Goodrich factories here in America, that Julliot saw the possibilities of his dirigibles in their adaptation to military use by the United States Government. With the foresight and determination so characteristic of his people he returned to France, where he lived practically the past two years in observing all types of aircraft and the success with which they were used by the Allied Governments. He also acted in an advisory capacity to the French Government during this period.

The present order for two of the Blimp type non-rigid dirigibles is being supplied under the personal direction of M. Julliot. This was the total number recently bid upon by The Goodrich Company, but now with the complete organization with which M. Julliot has surrounded himself, the facilities will permit of larger numbers being built in the near future in accordance with the aceptance of the offer of the entire Goodrich resources by the United States Government.

Domenjoz in Europe

New York City.—Mr. G. J. Kluyskens, well-known importer of Gnome and Anzani aviation engines, has recently received a letter from Jean Domenjoz, the famous exhibition pilot. Mr. Domenjoz is now with Bleriot in Buc, where he is in charge of reception and testing of the new Spads, which are equipped with 140 h.p. 8-cyl. V-type, two-cycle "Hispano Suise" motors.

The Spad is a small biplane of only 18 meters bearing surface and weighs 1,650 lbs., without gun, gasoline, pilot and oil. The speed is from 200 to 214 kilometers per hour. Mr. Domenjoz says that it is fearsome the way the machines climb; they climb at the rate of 3,000 metres in four to four and one-half minutes. Bleriot is now turning out five a day of these Spads, and the Spad people themselves turn out three a day.

He further advises that the Nieuport biplane is also giving very good satisfaction. Morane and Vedrine are also bringing out new machines and are now making tests with experimental machines.

Mr. Domenjoz also writes that the cost of living has gone up at least 50 per cent since he was last in Paris.

Mr. Domenjoz has a contract with Bleriot up to the end of May, and he will take the first boat in June to fill his flying engagements in this country.

Judgment Filed Against Aeronautical Society For $163.41

The New York Times, April 7th, publishes the following judgment filed in New York County, the first name being that of the debtor:

Aeronautical Society of America, Inc.—R. A. Chesebraugh, $163.41.

Personal Pars

Mrs. Lewis F. Burrough of Hastings, New York, has announced the engagement of her cousin, Miss Grace H. Oakey, to Robert M. Olyphant, Jr., son of Robert Olyphant of New York City. Mr. Olyphant is a member of the Aero Club of America and the First Flying Corps of New York.

HERDING SHEEP BY AEROPLANE

By JOHN E. HOGG

HERDING sheep from an aeroplane, scouting for lost herds, and signaling to herders and cowboys with smoke bombs and wireless is the latest use for the heavier-than-air vehicle evolved by J. Stanley Smith, a millionaire sheep ranchman, of Martinsdale, Meagher County, Montana.

Mr. Smith has purchased a plane, a 150 h.p. Martin tractor, and has enrolled for a course in aviation in the Gleen L. Martin school at Los Angeles. With the completion of his training he proposed to return to his estate in Montana, where he will inaugurate the use of aircraft in connection with the sheep raising industry.

"It takes a man on horseback four days to ride from one side of my ranch to the other," said Mr. Smith, in commenting upon his novel idea. "Hundreds of my sheep have been lost on the range, and have never been found by the herders. They died later from exposure and lack of attention. Last year I lost some 2,000 sheep. This loss I propose to eliminate by the use of an aeroplane.

"How I will do it is the simplest thing in the world. By flying over the wild portions of my estate it will be an easy matter to observe every herd of sheep from a comparatively low elevation. Sheep always go in herds, you know, seldom less than two or three hundred in a herd. When I sight a herd from the air, I will simply drop a smoke bomb, which will serve to indicate their location to the herders and men in the pack trains. I shall also have my machine equipped with wireless, which will enable me to communicate with the wireless station that will be installed on one of the motor truck of the pack train. In this way it will be possible for me to give definite instructions to my men as to the location of the lost herds, and for their getting to them by the most direct route.

"From the financial viewpoint the use of the aerial patrol on sheep ranches will result in an enormous saving. If I am only able to save half of the sheep that I have lost in former years the plan will pay for itself with big dividends thrown in.

"I will take this one plane back to Montana with me to give the plan a tryout, and if it works out, as I have every reason to believe that it will. I shall purchase at least five more planes for my ranch. Other sheep men in my vicinity have their eyes on the feasibility of the aerial patrol, and the success of the project will mean the universal adoption of the aeroplane by all the large sheep ranchers of the northwest."

Farmer Smith and his Martin tractor biplane in which he herds his sheep as described above

AMERICAN BATTLEPLANES

REAR ADMIRAL FISKE, whose inventions and achievements rank him with the leading naval authorities of the world, recently gave it as his opinion that one hundred large battleplanes carrying 3-inch guns would afford the defensive power of about 60,000 rifles.

In the memorandum Admiral Fiske pointed out that:

"If battleplanes have a field of usefulness in Europe, where the distances are very small and where the organization, training and strategical employment of large armies have reached a high state of development, do they not have a much wider field in the United States, where the distances are relatively enormous, and where the organization, training and strategical employment of large armies are arts almost unknown? Is it not possible that an immediate and strenuous development of battleplanes might save us from invasion, just as the Monitor saved us from the Merrimac?

"In case our fleet is defeated in the Atlantic during the next year, we shall not have an army that could not stand up against any European army that might land on our shores. But if we had a division of say one hundred battleplanes near New York, costing about three million dollars, we could certainly prevent the disembarkment, transit in boats to the shore, and landing of any force of soldiers, especially if the battleplanes were assisted by say two hundred small aeroplanes, dropping bombs. Similar divisions at other points, including one at the Panama Canal, could perform similar services, and the great speed of the aircraft would enable each division to guard a long extent of coast. A division of 100 battleplanes could go from New York to the Capes of the Chesapeake in three or four hours. They could be equipped with 3-inch guns. The muzzle energy of 100 3-inch guns is equal to the muzzle energy (and therefore destructive power) of about 60,000 soldiers' rifles.

"The size and power of the aeroplanes has already gone far beyond the limits set for its possible development by certain engineers only three years ago. The practical difficulties of making it larger still are quite apparent; yet, nevertheless, no theoretical limits to its size and power have yet been accepted by aeronauts. That the aeroplane is now the best single weapon against the submarine is conceded. That the aeroplane, and especially the battleplane, will rapidly advance is size and power within the coming year and afterwards, is the mature belief of many aeronauts; should we not therefore immediately investigate its capabilities, not only as a scout and accessory, but as a major instrument of warfare?

"I do not suggest the abolition of the soldier and his musket; but neither do I suggest the abolition of the boat pulled by the oars of rowers. I merely suggest that, as the boat pulled by rowers was superseded for large operations by the sailing ships, and as the sailing ship was superseded by the more mobile steamer with broadside guns; and as this type of warship has been superseded by the turret ships, and as the turret ship has been expanded into a super-dreadnought, so the soldier and his musket may be superseded for important operations by the immeasurably more powerful and mobile battleplane.

"If so, the more quickly we act, the better. 'Hindenburg never sleeps.' "

Those familiar with the activities of the multiple-motored machines in Europe—the Handley-Page, The German Fritz, the Italian Caproni, the various French "avion de chasse," and the Russian Sikorsky—know the effective service they have rendered, and relatively speaking they are just beginning to be used.

In the last two issues, AERIAL AGE has presented an article by F. Handley-Page, which ably sets forth "The Case for the Large Aeroplane," and the purpose of the present article is to present the facts concerning some of the leading twin-motored American machines.

The Curtiss Twin JN

Amongst the first successfully flown twin-motored machines, was the Curtiss JN military tractor, in which Victor Carlstrom, carrying Mr. Alan R. Hawley, president of the Aero Club of America, as passenger, made a flight from New York to Washington.

The Curtiss Model JN Twin-motored Tractor possesses all the inherent advantages which go to make up a successful military aeroplane. It has high maximum speed and fast climbing ability combined with a slow landing speed and great weight carrying capacity. Although it weighs but 2,110 pounds, empty, it has a useful load carrying capacity of 1,040 pounds.

Two Curtiss Model OXX 8-cylinder motors, one located to the left and the other to the right of the fuselage, give this battleplane an available 200 horsepower.

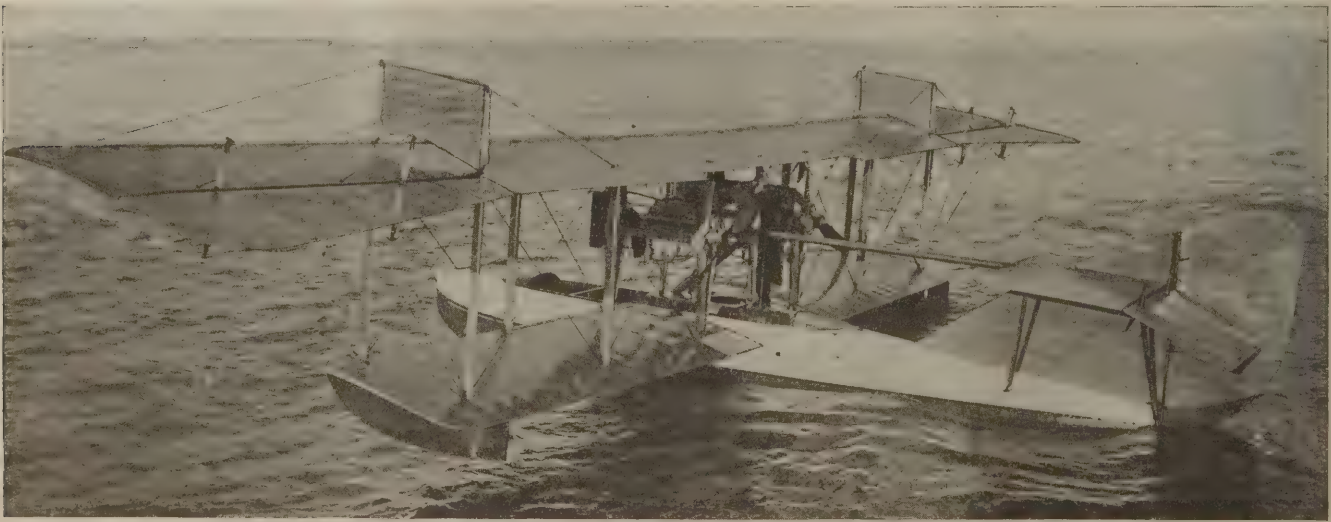
It has a maximum horizontal flight speed of 85 miles per hour, a minimum of 48 miles per hour, and a climbing speed under normal conditions, of 4,000 feet in 10 minutes. The machine will fly and climb on one motor.

The front cockpit is placed in the nose of the fuselage, giving to the observer or gunner seated therein an unobstructed range of vision and an extensive field of fire.

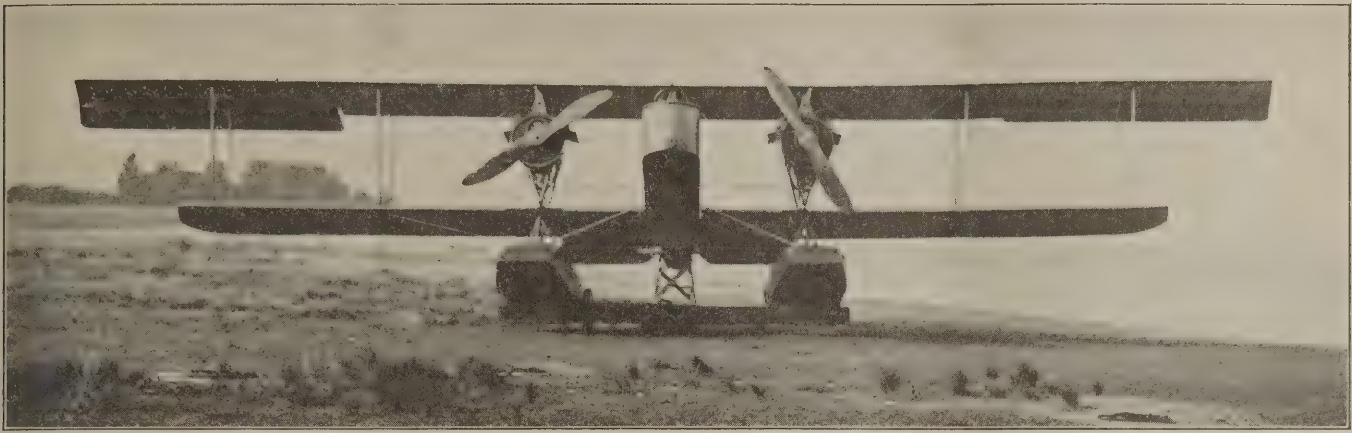
The twin-motored machine possesses several advantages over the single-motored type. The two propellers, turning clockwise and counter-clockwise, respectively, result in equalized torque and gyroscopic effects. The air streams which they produce also have a tendency to make the machine readily controllable under power. Without power, this machine assumes a moderate gliding angle which permits an easy and safe landing.

Another advantage gained by the use of two motors is a decrease, relatively, in the air resistance to the progress of the aeroplane through it. Because there is a smaller, total projected area of the machine lying in the propeller "slip streams" less power is consumed in overcoming head resistance and the surplus thus saved can be utilized for increasing speed or useful load carrying capacity.

By using twin motors it is also possible to equip with greater power without resorting to excessive propeller sizes and speeds.



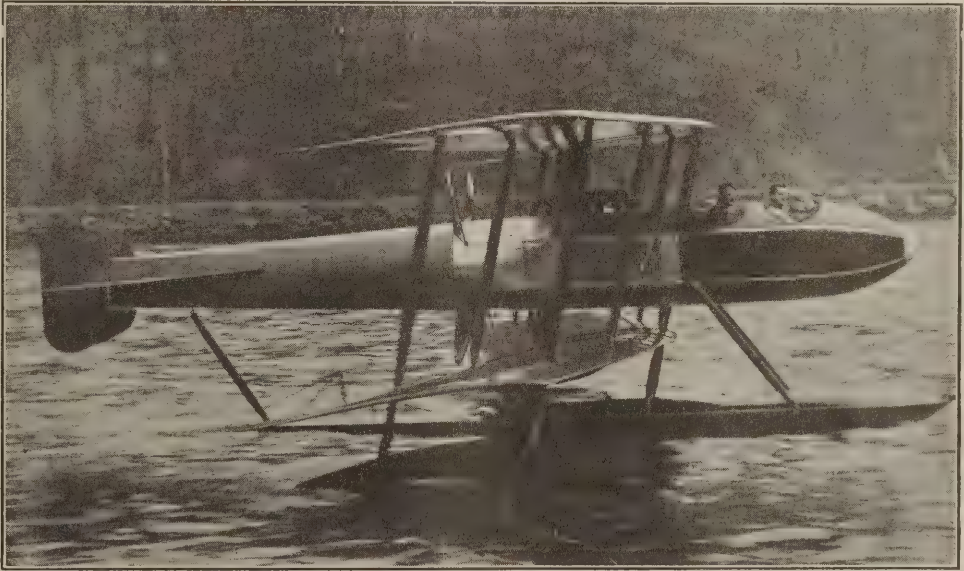
The five-passenger Curtiss cruiser of the America Trans-Oceanic Co., at Port Washington, L. I.



The twin-motored Curtiss Hydroaeroplane. Two 100 H.P. motors are used

Curtiss "Canada" Type

The "Canada" was a development of the Toronto Curtiss plant. A tractor biplane with two Curtiss OX2 motors, a span of 76 feet and a length from nose to tail of 28 feet. The length of the fuselage is 17 feet, and 32 inches wide. The machine was designed to carry two observers and pilot.



Gallaudet Seaplane constructed for the U. S. Navy, and equipped with two Duesenberg aviation motors

The "America"

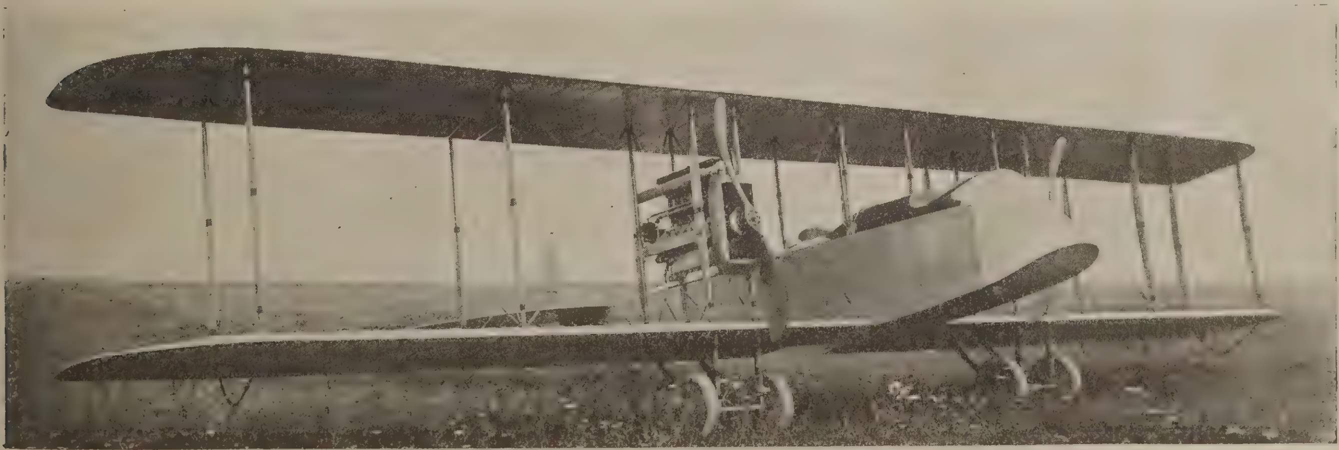
The "America" was the first twin-motored flying boat to be built by the Curtiss Company. It was constructed for Rodman Wanamaker in connection with his plans to cross the Atlantic in an aeroplane. The outbreak of the war upset the scheme, and the machine was sold to the British Admirality.

It had two 100 h.p. Curtiss motors, and could accommodate four men comfortably in its cabin.

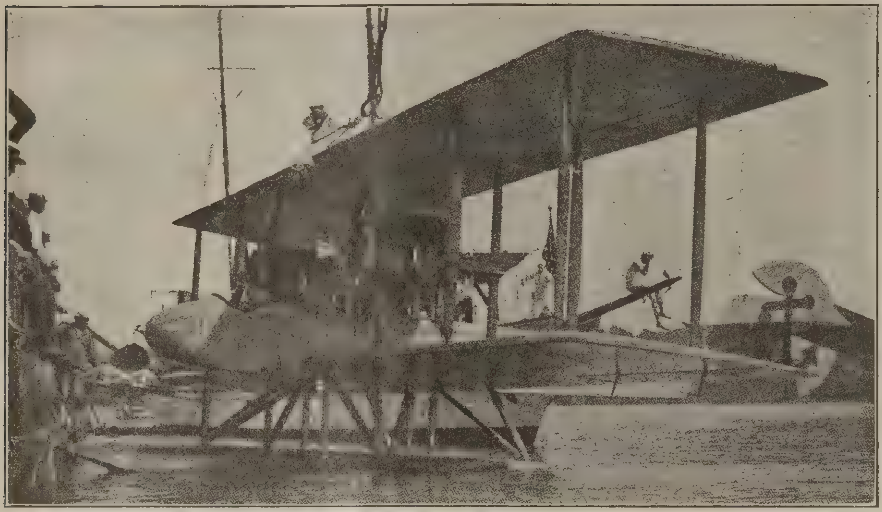
The "Super-America" Types

Containing every instrument and device that makes for comfort and safety, the Curtiss "Flying Cruiser" of the Super-America type is not only one of the best equipped flying boats in the world, but is the largest and most finely finished boat flown in America. First trials were made by David H. McCulloch, chief pilot of the America Trans-Oceanic Co., at Port Washington, L. I., in the early part of November. The machine handled beautifully, and gave its owners reason to believe it would fulfill the requirements for which it was designed.

Electric starters are provided for the motors. Automatic stability is obtained by the use of the Sperry Gyroscope, operated by Servo motors which are run by air fans.



Atlantic aircraft battleplane designed by A. S. Heinrich, and powered with two Aeromarine motors



Twin-motor hydroaeroplane constructed by the U. S. Navy

A large searchlight is located at the nose of the hull. There are dash lights, cockpit lights, rear seat lights, tail lights and red and green port and starboard lights on upper wing tips. Small lights are located at the top of all interplane struts, which cast their rays downward and along all wires, making the machine quite visible at night, facilitating landing and permitting the observation of all structural members while in flight. A "trouble light" on an extensionable lead is carried in the mechanic's cockpit, for use in making adjustments or repairs.

Generators for supplying the current necessary for the operation of the gyroscopes, lights and instruments, are fastened on the outrigger where their wind turbines are near the slip stream of the propellers. Each generator is of 55-watt capacity, producing 2 amperes at 22 volts when driven at 4,000 r.p.m. To avoid the possibility of damaging the gyroscopes by an excessive current as well as to provide current for the instruments, a storage battery is placed on the circuit. The battery is of 2 ampere hours capacity. The weight of the entire electric generating installation is under 70 pounds.

The supporting surface includes the upper and lower wings, the total area of which is 853.16 square feet. The aeroplane (dead load) weighs 2,240.10 pounds. Power plant and accessories (dead load), 1,316.50 pounds. Live load, consisting of passenger and pilot (330 pounds), fuel (558 pounds), oil (62 pounds), and the additional required load (150 pounds) totals up to 1,100 pounds. Grand total weight of aeroplane, power plant, accessories and live load, 4,656.60 pounds.

Loading calculated at 4,656.60 (divided by 853.16), which equals 5.46 per square foot. Load lifted per rated h.p. (4,656.60 divided by 200, equals ——) 23.28 pounds per r.h.p. Load lifted per brake h.p. (4,656.60 divided by 216, equals ——) 21.60 pounds per b.h.p.

General Dimensions: Planes, upper, 75 feet, 10 inches; Planes, lower, 48 feet; Chord, 7 feet; Gap, 7 feet, 6 inches; Length, overall, 39 feet; Net weight, 3,556 pounds; Weight, fully loaded, 4,656 pounds; Motors (2) Curtiss, 100 h.p., 200 h.p.; Speed range, 65-48 m.p.h.; Climb in 10 minutes, 2,000 feet.

The Curtiss H-12

The Model H-12 flying boat, built by the Curtiss Co., for the U. S. Navy, is the largest type of flying boat in the world. First trials are to be given it at Pensacola, Fla. Although the H-12s have been turned out in large numbers for use in European navies, the demonstration flights at Pensacola will be the first to have been made by such a machine in this country.

In spite of the gigantic proportions of the boat, it is easily controlled by one pilot. Four or five passengers besides the pilot can comfortably move about in the cockpit. The cockpit is entirely covered over by a hatch provided with celluloid windows permitting vision in all directions. This not only protects the occupants from the wind when in flight and spray when alighting, but also carries out the smooth effect of the hull to decrease wind resistance and skin friction.

Curtiss model twin J. N. Military Tractor

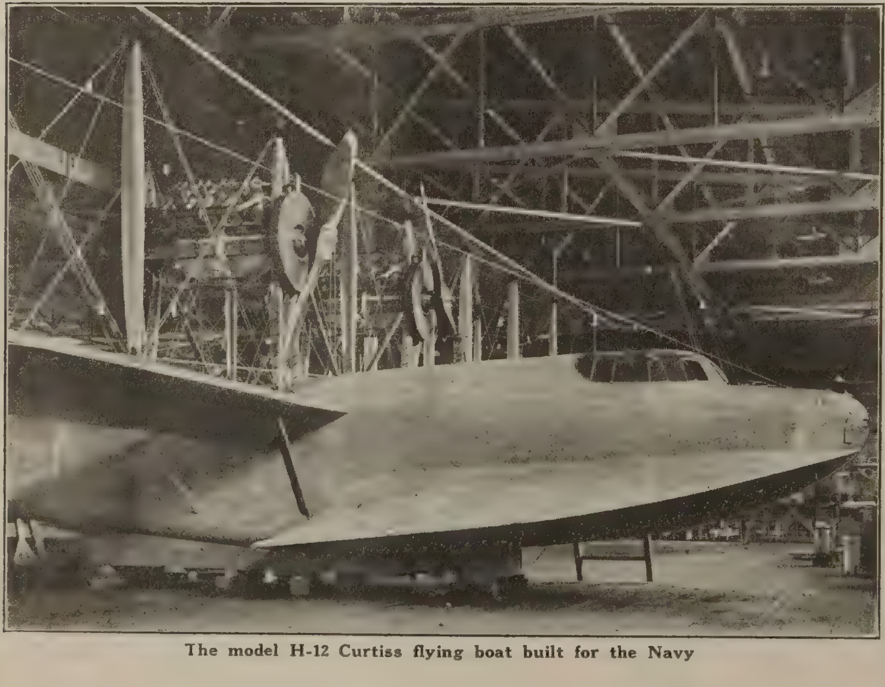
List of general dimensions, areas and weights: Wing span, upper plane, 92 feet, 8½ inches; Wing span, lower plane, 66 feet, 11½ inches; Total supporting surface, 1120.78 square feet; Gap between wings, 8 feet; Height overall, 16 feet, 9¼ inches; Net weight of machine, empty, 5,945 pounds; Useful load (as listed below), 2.044 pounds; Motors (2) each 200 h.p., 400 h.p.

Useful load is figured as being composed of pilot and passengers each weighing 170 pounds; oil, 148 pounds, and gasoline, 1,556 pounds. In shorter flights the quantity of oil and fuel can be decreased and passengers carried of equal weight.

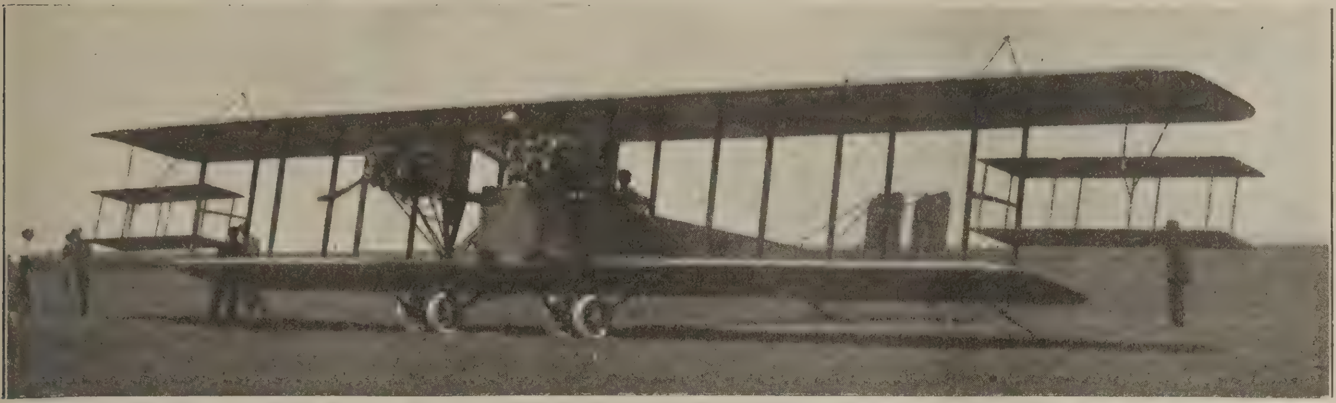
Twin motors of the Curtiss Model V2 are supported between the planes with the propellers in tractor position. Forward of the motor-carrying struts the circular radiators are located, through which the propeller shaft project. The V2 motor is an eight-cylinder V-type, four-stroke cycle, rated at 200 h.p. at 1,400 r.p.m.. Bore, 5 inches; stroke, 7 inches. Ignition is by two high-tension eight-cylinder magnetos and cooling by water circulated by a centrifugal pump. Two Zenith carbureters.

Gasoline consumption per b.h.p. hour, .54 pound; oil, .03 pound. Weight of each motor with propeller hub, but without oil or water, 690 pounds. Dead weight per rated h.p., 3.45 pounds.

The boat is expected to attain a speed of eighty-five miles an hour, and leaves the water at approximately fifty-five miles an hour.



The model H-12 Curtiss flying boat built for the Navy



The twin-motored Andermat Cruiser Aeroplane which has a wing-spread of 72 feet

The N. Y. Aero Construction Seaplane

The hydroaeroplane recently completed and tested by the N. Y. Aeroplane Construction Co., has a supporting surface of 820 square feet, twin Aeromarine motors, 100 h.p. each, and twin pontoons, weighs 2,700 pounds, and has room for a useful load of 1,700 pounds. Its maximum speed is 85 miles per hour, minimum, 43 miles per hour, and it has a flying radius of nine hours. Due to advanced type of pontoons and other features embodied in the plane, it rose from the water on test within fifty feet, Aviator W. Leonard Bonney flying. The pontoons can be replaced by land rigging.

The plane was designed and constructed under the supervision of Mr. Warren S. Eaton, who is a poineer in the aviation business, having designed and constructed planes for the Glenn L. Martin Co., of Los Angeles. He also designed and built four of the most efficient planes for Lincoln Beachy, which had their demonstration before people in the West.

The Twin-Motored Atlantic Tractor

The twin-motored tractor designed by Albert S. Heinrich, of the Atlantic Aircraft Co., made successful flights at Mineola, in the Summer of 1916, when aerial topedo carrying tests were made. The power plants were two Aeromarine six-cylinder motors.

As the fuselage projects well forward of the planes, a machine gun mounted on the nose is permitted a wide arc of fire. One of the tests at Mineola consisted of carrying a torpedo below the fuselage, which could be released at the will of the observer. The nature of the landing gear gives a good deal of clear space below the fuselage, affording an ideal location for suspending and releasing aerial torpedoes of large size.

General Dimensions: Top and bottom span, 48 feet; chord, 6 feet; gap, 7 feet; length overall, 28 feet, 6 inches; height, 11 feet; area, main planes, 550 square feet; area, stabilizer and elevators, 60 square feet; motors (2), 92 h.p. each, 184 h.p.

The Andermat Cruiser

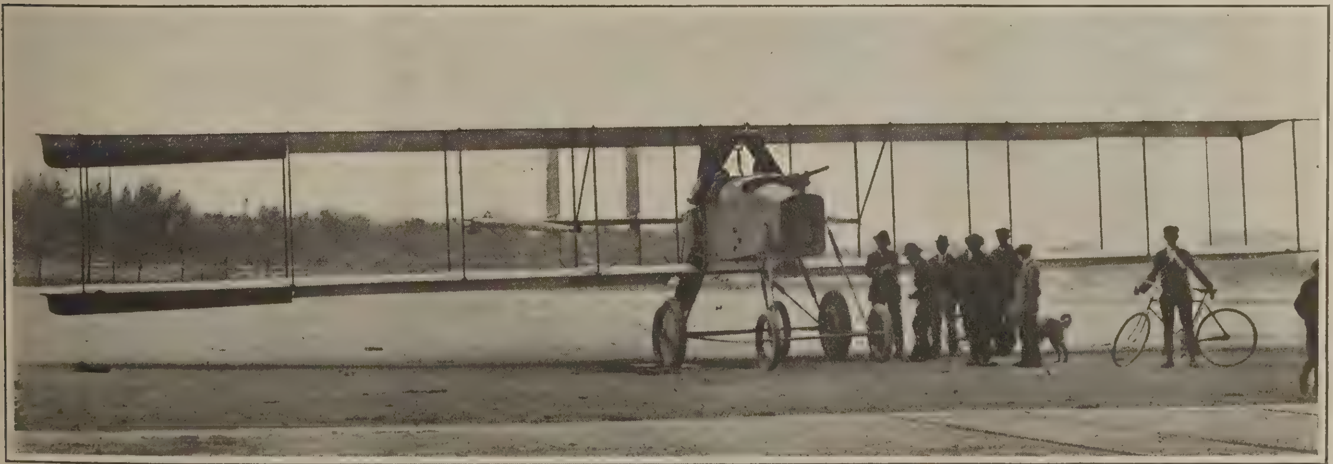
The Andermat cruiser, a twin-motored battleplane, was constructed at Sunnyvale, California, under the direction of W. G. Loomis. It has a wing spread of 72 feet and a length of 35 feet from nose to tip of the tail. The power plants are two 120 h.p. Andermat engines. The first machine constructed was flown successfully, and it is stated that plans are now under way for the organization of a large company to produce the machine in quantity.

The Gallaudet Seaplane

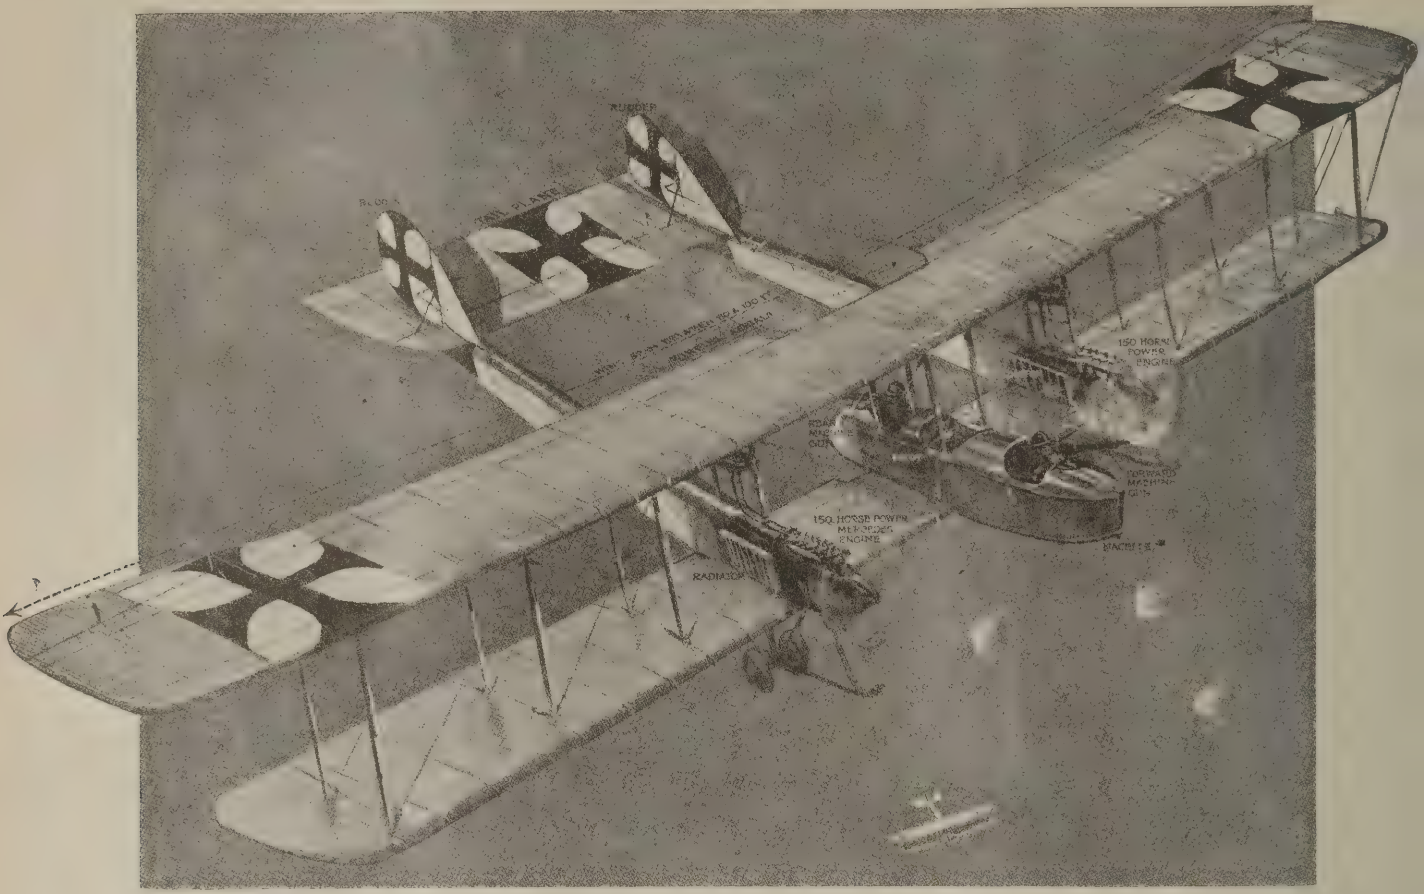
The Gallaudet seaplane combines the advantages of the pusher type with those of the tractor in that the pilot's and observer's views are unrestricted in all directions, the case with all pusher types, yet the seaplane possesses a fuselage, greatly lessening resistance. The machine is equipped with two Duesenberg engines of 150 h.p. each, driving two propellers. The part of the propellers nearest the center which absorbs power without producing any propulsive effort is inside the body so that the power usually lost in this portion is expended near the tips. The result is an increase in efficiency. The machine has a flying radius of 4 hours at 100 m.p.h. two engines running, or 11½ hours at 70 m.p.h. one engine running. The company is at work on a large order for the U. S. Navy.

Various Future Types

The companies in America who are engaged on the design and construction of twin-motored machines, the appearance of which may the anticipated this Spring and Summer, include the Aeromarine Plane and Motor Co., the Standard Aero Corporation, the Thomas-Morse Aircraft Co., The United Eastern Aeroplane Co., The Wright-Martin Aircraft Corporation, and The James V. Martin Aeroplane Co.



The large 60-foot Spread Voisin gun-carrier. This was the forerunner of the present smaller gun carriers and the newer and larger double-motored types. Note the six-wheel landing chassis, steel tube construction, small gap between planes and unique tail bearers. These tail bearers have since been discarded in favor of the regular steel tube outriggers



FOREIGN TWIN-MOTORED TYPES

Some of the more important twin-engine machines include the Sikorsky, the "Fritz," the Handley-Page, the Caproni, and the French "avion des chassé," the principal details of which are here given.

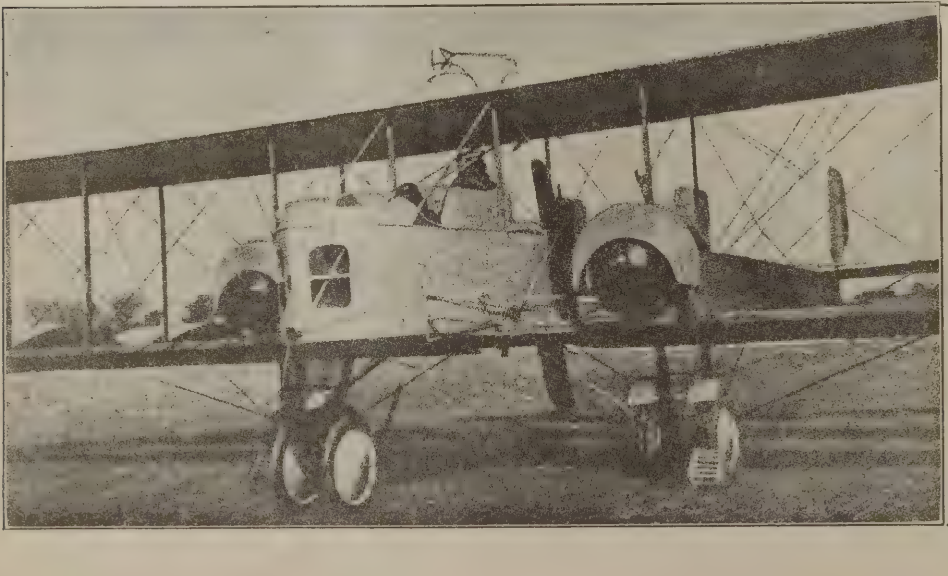
The Handley-Page

The twin-motored Handley-Page biplane carried twenty passengers in a test flight made recently at Hendon. Very little data is available concerning its dimensions, but it has been stated that it has a wing spread of about seventy feet, and a length over all of about 30 feet. The power plants are two Rolls-Royce motors. F. Handley-Page, designer, is one of the pioneer pilot-constructors in England, and he has many construction achievements to his credit. It would seem that his latest project would add to the sum total of his work.

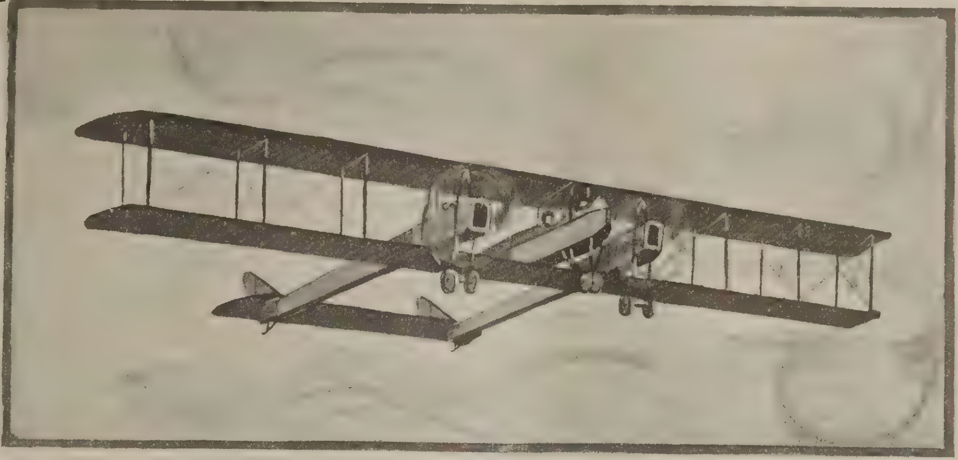
The "Fritz"

"Fritz" was the name given by the British aviators to the first German aeroplane to make its appearance over the trenches in Europe. It was somewhat graphically described in the *London Illustrated News* as follows:

"He is a big brute, anywhere between 80-foot and 100-foot span, and driven by two Mercedes engines of 100 h.p. to 150 h.p. each. These engines are placed in two narrow fuselages, whilst in the centre is a nacelle which contains seats for three men (two gunners and the pilot). The big machine remains aloft on patrol duty for six hours, his engines throttled down to their utmost limit, and thus enconomizing fuel. Should an enemy appear, the great watcher, some 8,000 feet to 9,000 feet above the Allies' trenches, suddenly accelerates to full speed. From the ground the giant engines can be heard, as they suddenly roar into full power, and the enormous ma-



A Caproni biplane of the latest type which has three Isotta-Fraschini, or Fiat, engines of 200 H.P. upwards. This machine is one of the most powerful "avions des chasse" in use in Europe



The Italian Caproni biplane, which is equipped with two Isotta-Fraschini motors

chine can be seen literally to swoop across the sky. With his two machine guns able to fire in any direction, he holds a great advantage over his enemies, and when he drives down upon them their only real chance is to dash for home at full speed. The Germans for a model have taken the Italian Caproni machine."

The Sikorsky

The first successful Sikorsky was completed in Russia but a few months before the outbreak of the great war, and was the result of years of experiments. One of the machines named the *Ilya Mouromets* was propelled by four Argus motors of 100 h.p.

It was asserted by the inventor that two of these motors could be put out of action without causing an accident. While the aeroplane was flying over St. Petersburg one day, one of the motors became frozen and stopped. The speed of the aeroplane was diminished, but it continued on its course, and presently one of the crew was able to thaw out the motor and start it again.

The *Ilya Mouromets* had a wing area of five times that of the ordinary Farman biplane. The metal fuselage, 65 feet long and the forward part of the fuselage contained a number of cabins extending over a length of 28 feet. The cabins had large windows on both sides and also windows in the floor for observation and photographic purposes. At night the cabins were lighted by electricity.

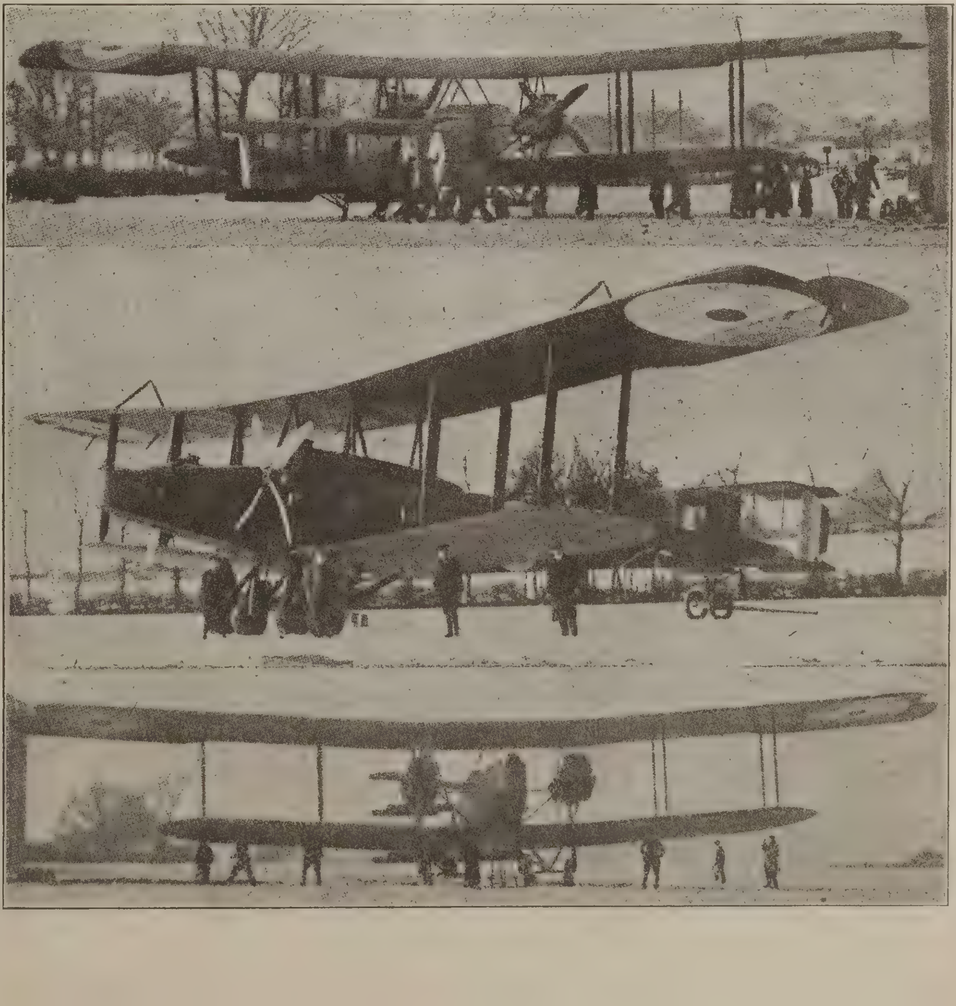
The total weight of the aeroplane was three and one-half tons. With a total development of 400 h.p. the *Ilya Mouromets* could raise a total useful weight of a little over one ton, besides nearly eight hundred-weight of fuel oil.

The mechanics moved about freely to attend to the motors and other parts of the machine without disturbing the equilibrium of the aeroplane while in flight.

During the past two years, giant biplanes of the Sikorsky type have been built in England, and equipped with Rolls-Royce motors, they have done excellent work.

The Caproni

The Italian Caproni, with two, three and four motors, has been built extensively, and used primarily as an "avion des bombardments." The spread varies from fifty to eighty feet and the motors used are Fiat, and Isotta-Fraschini.



Handley-Page, the designer of this machine, is one of the pioneer English pilot-constructors

SECOND ANNUAL REPORT OF THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

By WILLIAM F. DURAND, Chairman of the Committee

The National Advisory Committee for Aeronautics was established by Congress by act approved March 3, 1915. Under the law, the committee is charged with the supervision and direction of the scientific study of the problems of flight with a view to their practical solution, and the determination of the problems which should be experimentally attacked, their solution, and their application to practical questions of aeronautics. In the event of a laboratory or laboratories, either in whole or in part, being placed under the direction of the committee, the committee may direct and conduct research and experiments in aeronautics in such laboratory or laboratories.

The committee has twelve members, appointed by the President. As authorized by Congress, the personnel of the committee consists of two members from the War Department, from the office in charge of military aeronautics; two members from the Navy Department, from the office in charge of naval aeronautics; a representative each of the Smithsonian Institution, of the United States Weather Bureau, and of the United States Bureau of Standards; and not more than five additional persons acquainted with the needs of aeronautical science, either civil or military, or skilled in aeronautical engineering or its allied sciences.

During the past year there was one change in the membership of the committee, caused by the retirement of Lieut. Col. Samuel Reber, United States Army, who was succeeded on the committee by Lieut. Col. George O. Squier, United States Army, as officer in charge of the Aviation Section of the Army.

The organization of the Advisory Committee, as of October 5, 1916, is as follows: Prof. William F. Durand, chairman; Naval Constructor H. C. Richardson, United States Navy, secretary; Prof. Joseph S. Ames, Capt. Mark L. Bristol, United States Navy; Prof. John F. Hayford, Prof. Charles F. Marvin, Hon. Byron R. Newton, Prof. Michael I. Pupin, Brig. Gen. George P. Scriven, United States Army; Lieut. Col. George O. Squier, United States Army; Dr. S. W. Stratton, Dr. Charles D. Walcott.

Relation of Work of the Advisory Committee to Army and Navy

In the course of the past year a number of problems of importance to the Army and Navy have come to the attention of the committee, and steps have been taken toward aiding these departments in arriving at solutions of the problems presented. Report No. 11 on gasoline carbureter design, which has just been prepared, and an investigation of air propellers, which is about to be inaugurated by the committee, will both be of value to the military branches of the Government. In the exercise of its function for securing co-operation the committee has enlisted the interest of the Bureau of Standards in the determination of the characteristics of the materials entering into aeroplane construction and in particular into the construction of air propellers, and the Bureau of Standards is already engaged on these problems. Through its subcommittee on motive power, the Advisory Committee has effected an active co-operation between the Government departments concerned and the Society of Automobile Engineers, which it is expected will at an early date enable the committee to place valuable information at the disposal of the Government departments and the aeronautic industry in general.

Aerial Postal Service

At the annual meeting on October 5, 1916, a representative of the Post Office Department was present, at the request of the committee, and informed the committee of the unsuccessful efforts of the Post Office Department to inaugurate an aerial postal service in Alaska and from New Bedford to the island of Nantucket.

It was apparent that, although aviation has made great strides in the past two years, the conditions of both of these routes were so severe as to deter responsible bidders from undertaking this service. After discussion of the entire matter, the committee concluded that the time has arrived when it is perfectly practicable to inaugurate such air service, and recommends to Congress that the Post Office Department be authorized to establish one or more experimental routes, with a view to determining the accuracy, frequency and rapidity of transportation which may reasonably be expected under normal and favorable conditions, and therefrom to determine the desirability of extending this service wherever the conditions are such as to warrant its employment.

The Advisory Committee will, if called upon, assist and advise the Post Office Department in the undertaking above recommended.

Work of the Committee

During the past year the Advisory Committee has held two meetings—on October 15, 1915, and April 20, 1916. The business transacted at these meetings appears under the various subjects treated in this report. At the meeting on October 15, 1915, the regulations were amended to provide that the secretary of the Advisory Committee, who had been ex-officio secretary of the secretary of the executive committee, be made a full voting member of the executive committee. This amendment was approved by the President on October 25, 1915. At the meeting on April 20, 1916, the committee adopted an amendment to the regulations changing the date of the annual meeting to the Thursday after the first Monday in October in order to enable it to give consideration to the preparation of estimates of expenses for the following fiscal year, which are required by law to be submitted by October 15 of each year. This change was approved by the President under date of April 27, 1916.

The Executive Committee

For carrying out the work of the Advisory Committee the regulations provide for the election annually of an executive committee to consist of seven members and the secretary, ex-officio. The organization of the executive committee, as of October 5, 1916, is as follows: Dr. Charles D. Walcott, chairman, Secretary Smithsonian Institution; Naval Constructor H. C. Richardson, United States Navy, secretary; Prof. Joseph S. Ames, physicist, Johns Hopkins University; Capt. M. L. Bristol, United States Navy; Prof. Charles F. Marvin, Director United States Weather Bureau; Prof. Michael I. Pupin, physicist and electrical engineer, Columbia University; Lieut. Col. George O. Squier, United States Army; Dr. S. W. Stratton, Director Bureau of Standards.

The program of work approved by the Advisory Committee was entrusted to the executive committee for execution. The executive committee was directed to consider a program of investigation and procedure intended to carry into effect the purposes of the act creating the Advisory Committee and to report the same with recommendations. The executive committee accordingly held regular monthly meetings throughout the year, and in addition held three special meetings. The reports of work done by the executive committee and its recommendations have been approved by the general committee and are incorporated into this report.

To facilitate the work of the committee the following subcommittees were formed and progress has been made on the general lines indicated in the designations of these committees:

Relation of the atmosphere to aeronautics.
Standardization and investigation of materials.
Aeronautical nomenclature.
Radiator design.
Motive power.
Specifications for aeronautic instruments.
Design, construction and navigation of aircraft.
Site for experimental field.
Governmental relations.
Bibliography of aeronautics.

Technical Reports

During the past year, owing to the very limited funds available for the use of the committee, only one contract for a special report was placed. This was for an investigation and report on the subject of gasoline carburetor design. Technical Reports Nos. 8 to 12, inclusive, are submitted herewith as appendixes.

Report No. 8 prepared by the subcommittee on specifications for aeronautic instruments covers the subject of general specifications for aeronautic instruments. The object of this report is to acquaint manufacturers with the types of instruments required for aeronautic purposes and the conditions to be met in the uses of these instruments in connection with the navigation and operation of aircraft.

Report No. 9, covering the subject of aeronautical nomenclature, was prepared by the subcommittee on aeronautical nomenclature. The subcommittee charged with its preparation very thoroughly investigated the new terms which have come into use with the development of aviation and after consideration of such limited contributions as were available on this subject, and the comments of aviators of the Army and Navy, and of manufacturers, adopted this nomenclature for the purpose of eliminating the confusion that has already come into existence in the use of aeronautical terms. In the preparation of this nomenclature, it appeared unnecessary to define any terms already well established in other branches. Particularly, it appeared unnecessary to define such terms as are familiar to all users of automatic engines; so that the nomenclature adopted by the committee principally comprises terms that are peculiar to, or new in, aeronautics.

Report No. 10 is a preliminary report of progress in the design and construction of a suitable form of muffler for aeronautic engines. This is a rather difficult problem and requires a large amount of experimental work. In this preliminary report it is pointed out that there are other than exhaust noises to be contended with even more difficult of elimination. This special report was prepared and submitted by Profs. H. Diederichs and G. B. Upton, of Cornell University, Ithaca, N. Y., under contract made in June, 1915. As definite results have not as yet been attained, experimental work and investigation will be further pursued during the present fiscal year.

Report No. 11, previously referred to, is a very complete and valuable report on gasoline carburetor design and throws light on a rather neglected subject. This special report was prepared and submitted by Prof. Charles E. Lucke, of Columbia University, New York, N. Y.

Report No. 12, entitled "Experimental researches on the resistance of air," by L. Marchis, professor in the Faculty of Sciences of Paris, is an admirable résumé of the status of experimental research at the present time. It is not an original paper, having been translated from the French by Prof. William F. Durand, a member of the committee.

A report on the "Physics of the air" has been prepared by the subcommittee on the relation of the atmosphere to aeronautics and printed in pamphlet form by the Smithsonian Institution. This report should be valuable to aviation officers, who obviously desire to know the causes of atmospheric phenomena, as well as to practical aviators, as many of the results, especially those given in tables and diagrams, are in form for quick and easy use by the practical pilot. The report as published is an abstract from the complete report of that material which is of special interest to navigators of the air.

General Problems

The problems enumerated in the first annual report of the committee constituted the program of work during the past year. These problems are considered of immediate importance, and will be attacked on a larger scale by the committee as soon as funds are made available for the purpose.

A. STABILITY AS DETERMINED BY MATHEMATICAL INVESTIGATIONS.—The work inaugurated by Asst. Naval Constructor J. C. Hunsaker, United States Navy, on these lines has been extended, and is now being carried on by Prof. A. Klemin, who has succeeded Naval Constructor Hunsaker at the Massachusetts Institute of Technology. Prof. Klemin is endeavoring to reduce this problem to a practical form, which will permit of the determination of the proper proportions of the different elements of the aeroplane design in order to insure the desired qualities, and it is expected the committee will be able to obtain a report on this work during the coming year.

B. AIR SPEED METERS.—A number of engineers are engaged in solving this problem, and a preliminary design has been worked out at the Washington Navy Yard, and has shown fair results in actual service. Upon the completion of experiments the data relative to same will be available to the committee.

C. WING SECTIONS.—No direct investigation bearing on the improvement of the form of the wing itself has been made but work of considerable interest has been carried out at the Massachusetts Institute of Technology under the direction of Naval Constructor Hunsaker, and reports have been published in a number of aeronautical papers and in Smithsonian Miscellaneous Collection, volume 62, No. 5, June 30, 1916. These reports include discussions of the advantages to be gained by changing the relations and proportions of the upper and lower wings in a biplane arrangement and also the effects produced in the triplane arrangement. Investigations show that by giving the upper wing a strong stagger and a larger angle of attack than the lower wing it is possible to obtain practically any desired degree of stiffness longitudinally, and this can be done even without the use of stabilizing tail planes. This contribution places this feature of design in a very satisfactory condition, analogous to that of the design of ships, in which the metacentric height is made to suit the conditions of service. It appears that for general service, and particularly for military service, an aeroplane having a very moderate longitudinal stiffness and ample controls for modifying the attitude of the machine, combined with proper damping surfaces affords the most satisfactory solution.

D. Engines.—In addition to the investigation of mufflers reported last year, the committee has inaugurated an investigation of the subject of gasoline carburetors, but otherwise, due to the limited funds, no direct investigations have been carried on by the committee. However, the results of the meeting of June 8, 1916, when the committee held an open conference with representatives of several manufacturers of aeronautic engines, have rapidly accumulated, and through cooperation with the Society of Automobile Engineers, through the subcommittee on motive power, the committee is closely in touch with engine development and is cooperating in every manner possible, principally by bringing the War and Navy Departments in close touch with this society, and thereby the manufacturers, so that many of the problems of engine design are already well in hand.

E. Propellers.—Very recently the propeller problem has assumed considerable importance, due to the difficulties experienced with wooden propellers handling large power at high speeds of revolution. This problem has been particularly serious in the air service of the War Department on the Mexican border because of the severe climatic conditions, which have seriously affected the life of the propellers. These problems are principally problems of mechanical construction and not problems of design involving the form of the propellers or their efficiency, and on the latter subject no progress has been made, as far as is known to the committee, and no satisfactory engineering data is available for design purposes.

The committee has just entered into a contract with Prof. William F. Durand, which will be carried out at Leland Stanford Junior University for an investigation of models of propellers with a view to establishing engineering data for design.

F. Form of aeroplane.—This has already been referred to under "A".

G. Radio telegraphy.—No particular progress is reported on this line, although both the War and Navy Departments have carried on investigations on these lines, and considerable success has been attained in recent experiments in the Army.

The Navy has also experimented at Guantanamo and carried on work at Pensacola. The Bureau of Steam Engineering of the Navy Department has also provided a number of aeroplane radio sets, and the Bureau of Standards has developed a radio direction indicator which will be given practical trials in the naval service at an early date.

Physical Problems

Besides the more general problems, the following problems of a physical rather than aeronautical nature are of particular interest. These problems were noted in the first annual report, but, owing to the lack of funds, very little progress has been made toward their solution during the past year.

A. Noncorrosive materials.—Investigation of noncorrosive materials at the Bureau of Standards has been continued, but no report is yet available.

B. Flat and cambered surfaces.—No progress is reported.

C. Terminal connections.—No additional progress is reported.

D. Characteristics of constructive materials.—This work has been begun by the Bureau of Standards, but no report is yet available.

E. Generation of hydrogen.—The Bureau of Steam Engineering of the Navy Department has taken up this work in connection with the installation of hydrogen plants aboard ships, but no report is available.

F. Standardization of nomenclature.—This subject is covered by Report No. 9, which accompanies this report.

G. Standardization of specifications for materials.—This subject is an extremely broad one and is being handled by the committee in cooperation with the Society of Automobile Engineers. One prominent manufacturer of aircraft has already developed a very good set of specifications for his own use, but these specifications are more or less particular in form, because of the present unusual condition of the material market.

H. Bibliography of aeronautics.—Negotiations are under way for the issuance of a report bringing this subject up to date.

I. Collection, revision and issuance of reports covering the state of the art of aeronautics have not been undertaken as it now appears probable that it will be unnecessary because of the number of good publications which already exist.

J. Limitation of size.—No steps have been taken by the committee toward the solution of this problem. An interesting article on this subject by F. W. Lanchester, member of the British Advisory Committee for Aeronautics, is noted in the Scientific American of June 3, 1916.

K. Causes of accidents.—Although this problem is a serious one, the committee has not been able to inaugurate the work proposed.

Co-Operation With Aeronautic Industry

At the meeting of the executive committee on May 11, 1916, an important step was taken when it was decided to invite representatives of different aeronautic engine manufacturers to be present at a meeting of the executive committee, to discuss the engine problem with the committee with a view to bringing out clearly the difficulties encountered by manufacturers in meeting the exacting demands of aviators and with a view to a more complete understanding between the builders and users of aeronautic engines. Accordingly, the executive committee held a public session on June 8, 1916, at which were present representatives of various manufacturers of aeronautic engines and in addition to the members of the committee representing various Government branches, there were also present, on invitation of the committee, special representatives of the War and Navy Departments familiar with the practical problems involved in the use and development of aeronautic engines. The Naval Consulting Board of the United States was also represented.

The proceedings of this meeting, being of great interest to the aeronautic industry in general, have been given wide circulation by the committee. One of the results of the meeting has been the inauguration of an important movements for the development of satisfactory aeronautic engines. This will undoubtedly serve to stimulate cooperation between the Government departments—the principal users of aircraft at present—and the principal producers of aeronautic engines. Thus, the Advisory Committee has already inaugurated one of the most important services for which it was established. Through the agency of the thoroughly established organization of the Society of Automobile Engineers, many of the steps which impeded progress in the development of the automobile should be avoided in the further development of the aeronautic engine, and powerful and competent agencies brought to bear to aid in the solution of difficult problems.

From such information as the committee is able to obtain, it now appears that the aeronautic engine problem, which was in an unsatisfactory condition a year ago, has greatly improved.

Standards of Work

The Government agencies fully appreciate the necessity of the adoption of standards of work and are taking steps toward the securing of such standards. It is of the greatest importance that the manufacturers of aircraft should work in harmony with the Government, at present the principal consumer, and that they should come to definite agreements as to the standards of work necessary to facilitate production and repairs. The committee, through the subcommittee on motive power, is assisting in this work of cooperation.

Existing Facilities for Aeronautic Investigations in Government Departments

Limited facilities for aeronautic investigaions in Government departments were reported in the first annual report, and it is anticipated that extensive additions to the existing facilities will be developed during the year 1917.

Quarters for the Committee

In the appropriation for the expenses of the committee for the fiscal year 1917, provision was made for the rental of quarters. The committee reports that quarters in the Munsey Building, adequately meeting the needs of the committee at present, have been secured. However, the increase in work contemplated by the committee, and authorized in the last appropriation, will require additional office space, and the committee recommends that the amount for office rent be increased as indicated in the estimates of expenses for the next fiscal year.

Financial Report

Out of the appropriation of $5,000 for the expenses of the committee for the fiscal year 1916, the committee reports expenditures and obligations during the year amounting to $4,904.28, itemized as follows:

Expenditures and Obligations Incurred Under Appropriation "Advisory Committee for Aeronautics, 1916"

Traveling expenses	$862.70
Furniture and equipment	363.57
Printing	419.60
Stationery	52.42
Telegrams	5.99
Clerical services	1,200.00
Special report (Carburetor investigation by Prof. Charles E. Lucke, of Columbia University, New York, N. Y)	2,000.00
Total	$4,904.28
Balance turned into treasury	95.72
Amount of appropriation	$5,000.00

Estimates and Recommendations

The following estimates of expenses for the fiscal year 1917-18 have been submitted by the committee in due form:

For scientific research, technical investigations, and special reports in the field of aeronautics, including the necessary laboratory and technical assistants: traveling expenses of members and employees; rent (office in the District of Columbia not to exceed $1,500); office supplies, printing and other miscellaneous expenses; clerks; draftsmen; personal services in the field and in the District of Columbia: *Provided,* That the sum to be paid out of this appropriation for clerical, drafting, watchmen and messenger service for the fiscal year ending June thirtieth, nineteen hundred and eighteen, shall not exceed $12,000; in all, $107,000.

It is strongly recommended by the committee that the next appropriation for the direction and conduct of research and experiment in aeronautics, and the committee's work in general, be made in lump sum with limitations only on clerical and drafting services and office rent in the District of Columbia.

For the fiscal year 1916-17 there was appropriated $85,000, as follows, which became available August 29, 1916:

Traveling expenses of members and employees		$2,000
Two technical assistants, at $2,500 each	$5,000	
One clerk	1,500	
One clerk	1,000	
One draftsman	2,000	
One draftsman	1,000	
Two laborers, at $660 each	1,32[illegible]	
Three mechanics, at $1,200	3,600	
		15,420
Rental of office		1,200
Supplies		7,800
Special reports		5,000
Movable combination field office, machine shop, dynamometer shed, hangar and power plant		15,000
Dynamometer carriage and truck		18,000
Aeroplane, including motor		10,000
Transmission dynamometer		1,000
Ripograph		1,000
Stabilizer		1,500
Anemometers, barographs, inclimometers, incidence indicators		1,500
Miscellaneous supplies, spare parts for operation of field plant		5,580
Total		$85,000

Owing to the many changes that have occurred in the rapid advance in the development of the art of aeronautics, it will be necessary to obtain further authority before a considerable portion of this appropriation can be used to the best advantage. The committee therefore also recommends that authority be granted to expend any remaining balances of the appropriation for the fiscal year 1916-17 under the same terms recommended for next year's appropriation. This would leave the committee free to use its funds in the most effective manner and transmit to Congress an itemized account of expenditures in its annual report.

Conclusions

The carrying on of the work authorized in the last appropriation depends largely on the availability of a suitable field for the location of the field laboratory and its equipment. In the last appropriation for the War Department Congress authorized the securing of fields for Army purposes, and the War Department has called on this committee for its advice respecting the conditions governing the selection of a suitable site for a proving ground for aircraft.

It seems to the committee that considerable advantage would be gained if the site selected for the War Department would also be such as to be suited to the requirements of this committee, as well as to the Navy Department, and, with this purpose in view, the committee has solicited the advice of both the Navy and War Departments in this matter. As a result the committee has been able to advise each as to the requirements of the other and of this committee in the location of such a proving ground, and the site finally selected by the War Department met with the approval of that department and of this committee. Neither this committee nor the Navy Department has authority or funds available for purchasing a site, the War Department only having authority and funds.

It is contemplated that a part of any site selected by the War Department may be made available for certain uses of the Navy Depart-

HOW YOU CAN JOIN THE AVIATION SECTION, SIGNAL OFFICERS' RESERVE CORPS

To answer the inquiries of the hundreds of applicants who wish to join the Aerial Reserve Corps the military authorities have issued a circular which answers the queries, as follows:

1. Q.—What is the Officers' Reserve Corps?
   A.—The Officers' Reserve Corps is a body of civilians who have received five-year commissions from the President of United States as Officers in the reserve of the regular army.
2. Q.—What is the Aviation Section, Signal Officers' Reserve Corps?
   A.—The Aviation Section, Signal Officers' Reserve Corps, is that portion of the body above mentioned which acts as a reserve for the Aviation Section of the regular army, in the same manner that the Medical, Engineer, Artillery, and other sections of the reserve, act as reserves for the corresponding organization in the regular service.
3. Q.—What obligations do I incur by entering this reserve corps?
   A.—In entering this reserve corps you are obligated to serve fifteen days per year in time of peace. In time of war or threatened war, you are subject to the call of the President. You cannot, however, be called out in a lower grade than that in which you are commissioned.
4. Q.—What are the qualifications required?
   A.—The qualifications required are three: mental, moral and physical.
5. Q.—What are the mental requirements?
   A.—The mental requirements are these: The applicant must show that he possesses a college education or its equivalent in experience of a military, technical, executive or other nature, which would enable the Board to waive the strict requirements necessitating a college education.
6. Q.—What are the moral requirements?
   A.—The moral requirements are established by letters of recommendation from three reputable persons. In the case of previous military service on the part of the applicant, he must submit statements of satisfactory service.
7. Q.—What character of physical examination must I pass?
   A.—The physical examination is the same as that required of applicants for aviation service in the regular army. It is a thorough examination lasting about two and one-half hours, which should be passed by the average man, free from organic disability and in good health. Special stress is laid upon good hearing and eyesight.
8. Q.—What are the flying qualifications?
   A.—The applicant must pass, before being commissioned, the Reserve Military Aviator's flying test. Unless he can pass this flying test he will not be given a commission. He will be assisted by the United States in obtaining the training necessary to fit him for a commission, provided he meets the other requirements prescribed above.
9. Q.—How long will course of training be?
   A.—The course of training will ordinarily take at least three months.
10. Q.—What kind of training will I undergo?
    A.—You will be required to undergo both a military and an aviation training to fit yourself for the position of an Officer Aviator.
11. Q.—Where will this training take place?
    A.—This training will take place at schools maintained under the supervision of the War Department. One of them is now established at Mineola, Long Island, N. Y., another at Memphis, Tenn., and others will be opened as opportunity permits. Civilian schools may also be designated by the War Department. At present there are two of these, the Curtiss Aviation School at Newport News, Va., and at Miami, Florida.
12. Q.—What expense will I incur?
    A.—All expenses will be paid by the United States if enlisted in the Aviation Section, Signal Enlisted Reserve Corps.
13. Q.—Do I have to enlist in the Enlisted Reserve Corps in order to receive Aviation training?
    A.—No. You can receive instruction and pay your own living and travel expenses. While receiving training at your own expense, however, you will be required to attend regularly both the military and aviation instruction courses.
14. Q.—What is the pay of the non-commissioned officer grades to which I might be assigned by enlistment?
    A.—You will be enlisted as Sergeant in the Enlisted Reserve Corps, the actual pay of which will be $36.00 per month, which with allowances for food, clothing, etc., will be brought to the equivalent of approximately $75.00 per month.
15. Q.—What rank will I have on completing the prescribed course?
    A.—On completing the prescribed course you will be given a rank as a 1st Lieutenant in the Aviation Section, Signal Officers' Reserve Corps, and placed on the inactive list. However, if in the opinion of the Secretary of War, you have special qualifications, he may, with your consent, retain you on active duty as long as there are funds available for that purpose and for such a period as he (Secretary of War) may elect.
16. Q.—What are the pay and allowances of this rank on active service?
    A.—The pay and allowances of this rank are as follows: Base pay $166.66; Commutation of Quarters (where no public quarters are available) $36.00 per month. In addition, while on flying duty you will be granted a 25% increase of pay.
17. Q.—If I am enlisted in the Enlisted Reserve Corps and my services prove unsatisfactory am I required to serve out my enlistment?
    A.—No. If your services prove unsatisfactory or in the opinion of the Officer in Charge of Training you have not the qualifications of a flyer, you will be discharged, or if training at your own expense, you will be dismissed.
18. Q.—When would I have to start training?
    A.—You would be required to start training as soon as you are assigned to a training school and continuing for three or more months.
19. Q.—How could I withdraw during the course?
    A.—If you desire to withdraw during the course, you must submit an application for discharge stating your reasons.
20. Q.—Where do I apply for information?
    A.—Apply for information to the following:
    1. The Chief Signal Officer of the Army, Washington, D. C.
    2. The President, Aviation Examination Board, Mineola, L. I., N. Y.
    3. The Aviation Officer, Central Department, Chicago, Ill.
    4. The Aviation Officer, Southern Department, San Antonio, Tex.
    5. The Commanding Officer, Signal Corps Aviation School, San Diego, Cal.
21. Q.—What steps must I follow to secure admission to this course of training?
    A.—To secure admission to this course of training you must:
    1. Write to any of the above for application blanks.
    2. Fill out required blank and return it.
    3. Present yourself for physical examination at time prescribed by the Examining Board.
    4. Appear before the Board at time prescribed by them for mental and moral examination.
    5. If accepted by the Board, you will be recommended for enlistment with a view to securing the necessary aviation training to qualify yourself for a commission. If so recommended, you will be ordered to report for enlistment at an enlistment depot. Upon being enlisted, you will be required to submit an application requesting that you be assigned to active duty at any Aviation School.
    6. Application will be approved, and you will be assigned to duty at a designated school for aviation training.
22. Q.—After passing the prescribed flying tests, do I have to accept a commission in the Aviation Section, Signal Officers' Reserve Corps?
    A.—When you are accepted for training and before you can start same, it will be necessary for you to make a signed statement on honor to the effect, that after pasing the prescribed flying tests satisfactorily you will accept a commission in the Aviation Section, Signal Officers' Reserve Corps.

D'ORCY'S AIRSHIP MANUAL

INTRODUCTION

D'Orcy's Airship Manual—the first installment of which is herewith published—is the result of a methodic investigation which was undertaken by the writer for the purpose of presenting an exhaustive but tersely worded register of the world's airship production, such as has not hitherto been available.

In principle *D'Orcy's Airship Manual* furnishes, whenever available, complete data for every airship of 500 cubic meters and over, which has been laid down from 1834 to August 1st, 1914. Smaller airships are listed only if they embody unusual features. In order to present a comprehensive view of each country's share in this novel industry, every airship is listed in chronological order under the name of her builder and all airship builders are listed in alphabetical order, according to countries. As to the airships laid down since the outbreak of the Great War it has been attempted to furnish the most complete and up-to-date information regarding the vessels built by the Central Powers and the neutral countries; data regarding recent airship constructions of the Allies had to be withheld for military reasons, unless previously published.

A complete list of the world's airship harbors is appended to the airship register.

The hitherto customary division of airships into the rigid, semi-rigid and non-rigid types—which was based on primitive and now obsolescent conceptions—has been found totally inadequate to express the features of novel sub-types which have more recently been produced; it has therefore been deemed advisable to adopt a new nomenclature, based on the constructional features of the hull which alone permit fundamental differentiation.

Whereas every airship hull presents to the relative wind an essentially rigid body, it follows that the term "rigid" cannot logically be applied to one particular airship type, the same argument barring also the terms "semi-rigid" and "non-rigid". Consequently all airships in which the shape of the hull is rendered permanent by means of a rigid structure, the hull frame, are here termed *structure airships,* whereas all those in which the shape of the hull is maintained through an excess of inner pressure, relative to the atmospheric pressure, are here listed as *pressure airships.* The latter are further subdivided, according to their suspension system, as follows:

(1) The *girderless type,* in which the load, carried on a short car, is directly distributed over the hull by means of branched suspension ropes attaching to hems which are sewn onto the hull. (Example, *Parseval.*)

(2) The *car-girder type,* in which the load is distributed over the hull by means of a long girder hung thereto, part of which is fitted as a car. (Example, *Astra.*) A divergent application of this principle consists in fitting a short car with fore-and-aft out-riggers (ex. *Koerting*).

(3) The *Keel-girder type,* in which the load, carried on a short car, is distributed over the hull by means of a girder attached to the underside of the hull. This girder may be built into the hull (ex. *Lebaudy*) or be hung thereupon (ex. *Gross-Basenach*); it may be articulated (Italian Army airships) or entirely rigid, with a car contained in its under part, thus doing away with suspension ropes (ex. *Forlanini*).

(4) The *Tension-truss* or *Astra-Torrès type,* in which the load is distributed over a hull of trefoil section by means of a truss contained within the hull and a branched suspension attaching thereto.

The "tension truss" consists of four cables running from bow to stern, three of which are sewn onto the hull at the intersection lines of the three lobes and are trussed to a fourth cable which follows the imaginary axis of the hull. When the hull is under pressure, the truss is under tension and acts as a girder which transmits the load *evenly* over the entire hull. Thanks to this feature, airships of the tension-truss type can be kept rigid, while under way, with an excess of pressure of only 3 to 4 mm water, whereas all other pressure airships require an average pressure of 25 mm water.

(*Continued on page* 153)

AUSTRIA

Boemches (Captain F.), Vienna—Builder of a pressure airship of the car-girder type. Girder consisting of a short car fitted with bow-outrigger only. Height control through lifting planes and compensating ballonets.

AUSTRIA—(Continued)

Haenlein (Paul), Vienna—Builder of a pressure airship of the keel-girder type. Height control through ballast shifting.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (m c)	Power (h p)	Speed (k m)	Notes
1	**Haenlein** (December, 1872)	**50.4**	**9.2**	**2,400**	**3**	**4.5**	Experimental airship—One Lenoir gas engine fed by the foal-gas contained in the hull; one pusher-screw. The trials disclosed the inadequacy of the power-plant, which barely enabled the airship to make any headway.

Koerting (Maschinenbau A. G.), Vienna—Builders of a pressure airship of the car-girder type. Girder consisting of a short car with two outriggers. Height control through two compensating ballonets and trimming tanks, the latter being operated by compressed air.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (m c)	Power (h p)	Speed (k m)	Notes
1	**M. III.** (January, 1911)	**68**	**10.5**	**3,600**	**150**	**49**	Austrian Army airship—Two Koerting engines; twin-screws. Ballonets: 900 mc. A fairly successful vessel. Was accidentally destroyed on June 20th, 1914, over Schwechat (near Vienna) through being rammed by a military aeroplane. The crews of both aircraft perished.

Motor-Luftfahrzeug Gesellschaft, Vienna—Builders of pressure airships to various designs.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (m c)	Power (h p)	Speed (k m)	Notes
1	**M. I.** (November, 1909)	**50**	**8.6**	**2,450**	**100**	**44**	Austrian Army airship—Built to the designs of the Luft-Fahrzeug-Gesellschaft (Parseval's patents). Girderless pressure type. Height control through two compensating ballonets and self-shifting car. Ballonets: 400 mc. One Austro-Daimler engine; one pusher-screw. Best endurance: 200 km. in 7 hrs. Dismantled in 1913.
2	**M. II.** (May, 1910)	**70**	**10.9**	**4,800**	**130**	**45**	Austrian Army airship—Built to the designs of Messrs. Lebaudy Frères. Keel-girder pressure type. Height control through lifting planes. Ballonet: 1,300 mc. One Austro-Daimler engine; twin-screws. Designed endurance: 10 hrs. Best altitude: 1,350 m. Dismantled in 1913.

Renner (A. & J.), Gratz—Builders of a pressure airship of the car-girder type.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (m c)	Power (h p)	Speed (k m)	Notes
1	**Estaric** (July, 1909)	**32**	**6**	**700**	**40**	**35**	Exhibition airship—One Puch engine; one tractor-screw. Was wrecked by the storm on Nov. 28th, 1910, while landing.

Stagl & Mannsbarth, Vienna—Builders of a pressure airship of the car-girder type. Height control through lifting planes, swivelling screws and compensating ballonets. Four compartments.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (m c)	Power (h p)	Speed (k m)	Notes
1	**Austria** (1911)	**91**	**13.2**	**8,150**	**260**	**65**	Experimental airship—Four ballonets: 2,500 mc. Two Austro-Daimler engines; two pairs of twin-screws and two swivelling screws, one fore and one abaft. Best endurance: 8¼ hrs. Dismantled in 1914 and sold at auction.

This excess of pressure is generated on all pressure airships by means of one or more *ballonets* or bladders which are located in the bottom of the hull and can be inflated with air through a fan-blower. A contraction of the gas and the resulting loss of volume and deformation of the hull are thus compensated by an expansion of the ballonet; on the contrary, an expansion of the gas beyond a certain limit (generally 30 mm water) will open the ballonet valves and receive the pressure without loss of gas, through the only escape of air. Should, however, the pressure still rise in spite of the open ballonet valves the pressure within the hull will be relieved by the automatic gas valves which are generally timed to open at 35-40 mm. water.

On certain pressure airships two ballonets are fitted which can respectively be pumped full of air whereby the vessel's trim may be changed without the use of lighting planes (elevators). The latter are chiefly employed on structure airships; on pressure airships their use is much less general, owing to the difficulty of aligning the elevators with the centre of resistance. Changes of trim can also be effected by means of communicating water tanks and, lastly, through lifting screws which may be of the stationary or swivelling type. The latter may also be employed for steering in the horizontal plane, although the use of a rudder is practically generalized.

Fore-and-aft oscillations, in other words *pitching* and *yawing*, are counterbalanced on practically all modern airships by means of surface fins, fitted on the stern, which have long since displaced the inflated fins of cylindrical or pear-shaped design.

On modern airships the shape of the hull is a matter of the greatest concern, lest undue impact and frictional resistances be encountered while under way. The best presently known hull shape, as determined by aerodynamic research work, is one six diameters long, with the master diameter located at about 40 per cent. overall length aft of the bow and with the bow blunter than the stern, both ends tapering and well rounded off.

Less attention has thus far been paid to the construction of the car, which on pressure airships is usually of rectangular section, although it would seem obvious to make it of streamline shape, as outlined above.

Quick computation of airship performances can be arrived at through the following basic laws.

(1) One cubic meter (1 mc) of pure (electrolytical) hyrogen at 15° centrigrade and 760 mm barometric pressure lifts 1.13 kilograms (kg);

(2) The lift *decreases* by 4 per mil of its value whenever the temperature *increases* by 1° centigrade and vice-versa;

(3) The lift *decreases* by 1 per cent of its value whenever the barometric pressure *decreases* by 1 per cent of its value and vice-versa;

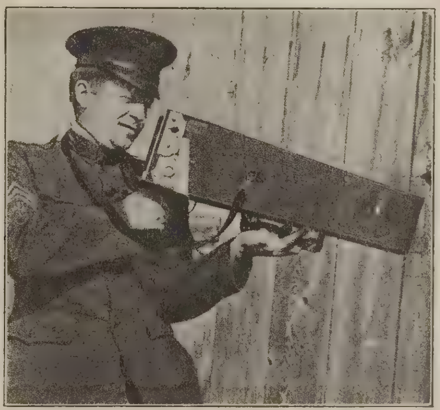
(4) The barometric pressure *decreases* by 1 per cent of its value whenever the altitude above sea-level *increases* by 80 meters.

In compliance with the advice given by the National Advisory Committee for aeronautics, all data in *D'Arcy's Airship Manual* are expressed in the metric system. For the convenience of readers unfamiliar with the metric system the approximate equivalents of the units employed are herewith given in English measures:

1 meter (m) = 3 1/3 feet.
1 kilometer (km) = 6/10 statute mile.
1 cubic meter (mc) = 35 1/3 cubic feet.
1 kilogram (kg) = 2 1/5 pounds.

(To be continued)

THE EASTMAN AEROPLANE CAMERA



THE product of four years of experimenting and testing, a camera which is said to be admirably suited for aeroplane work, has been perfected by the Eastman Kodak Company, according to an announcement by George Eastman.

Following tests at the naval aviation station at Pensacola, Fla., and on the Pacific coast, in which pictures of impressive clearness and detail were taken at altitudes ranging from 3,500 and 5,000 feet with the aeroplanes going eighty-five miles an hour, the Government has asked the immediate delivery of twenty cameras and a bid on a contract for sixty additional.

The new camera is a box two feet long, carries a pistol grip, gun sight and trigger, and when in use will be pitched, most of the time, at an angle of forty-five degrees. This slant will give the camera a wider sweep and make it of infinitely more value than the machines now in use on English planes which are adjusted to the bottom of the plane, with the shutter controlled by means of a cord.

It is understood that an aerial photographer with the British flying corps who wishes to take a shot, pictorially speaking, must be plumb above his object. In case he misses or overrides, he is compelled to circle and come back over the certain bit of topography, trench or ambush that he wishes to snap.

The Eastman camera carries, among other devices, a safety shutter on the end that is pointed toward the earth, as a protection against fog and the possibility of spray or mist blurring the glass. The camera weighs about fifteen pounds.

Midway between the front and the back of the case are buckles for the straps to go over the shoulders of the operator, thus allowing him the free use of his hands in an emergency. The machine will rest against the body of the aviator, which will form a cushion much on the order of a floating axle in an automobile.

William F. Folmer, manager of the Folmer & Schwing division of the Eastman Company, is given major credit by Mr. Eastman for the development of the aeroplane camera. When the Wrights began to fly several years ago, Mr. Folmer appreciated that a new field of navigation was opening and that the air, like the land, would find need for the camera.

The start was made by sending up a camera on kites suspended from captive balloons. A winged turbine advanced the film and reset the shutter, but the results caused despair. After months of experimenting one picture—a bird'seye of Kodak Park that was enlarged and now hangs in Mr. Eastman's office—was obtained.

The next step was taken with a graflex, which gave fair satisfaction. The chief fault of this method rested with the bellows. A wind striking the bellows created a tremor, it was found, and blurred the pictures.

When the Eastman Kodak Company began its third attempt to find a suitable instrument for air work, it prefaced the actual building of a camera by a world-wide survey of what other countries had done. Nothing was found to encourage them to pattern after any camera in use abroad. Whatever it was to have, it was finally decided, was to be had only through domestic genius. The aeroplane camera which has proved acceptable to the Government is the outgrowth of Folmer persistence.

The graflex focal plane shutter with which the new instrument is equipped is capable of speed from time to 1-1000th of a second. It is said that if an aeroplane accomplished the highly impossible speed of 300 miles an hour in the air, it would still be possible to arrest the object with the aeroplane camera.

Roads, cow paths and shrubbery taken from a height of 5,400 feet at Pensacola are remarkably distinct in the prints, four by five inches. They were caught with the shutter working at a speed of 1-295th of a second.

The camera will be built to use both plate and film. The model pictured on this page employs plates, the movement of the plates being regulated by the gun trigger. Such speed can be obtained with six plates, it is said, that a perfect panorama can be obtained by swinging the camera.

The lens in the new camera was made by the Bausch & Lamb Optical Company, and the glass for the lens was turned out in the company's own furnaces. This is regarded as conclusive proof that the homemade lenses are fully as good as those formerly imported from abroad and particularly from Germany.

(*Continued from page* 149)

ment and of this committee, or, if this is not approved, additional territory adjoining the War Department site can be obtained for these purposes.

The committee strongly recommends that the activities of the War and Navy Departments and of this committee on these lines should be carried out in as close proximity as is possible, to their mutual interest and the advantage of the Government.

The site contemplated by the Army is on a branch of the Chesapeake Bay, sufficiently remote from the entrance of the bay to insure reasonable immunity from interference due to the operations of a possible enemy. The location is such as to be readily accessible to Government officials located in Washington who have the direction of the important developments contemplated. It is also reasonably accessible to the principal manufacturing centers of the East, and therefore to the principal manufacturers who are interested in the production of the devices necessary to the War and Navy Departments.

The climatic conditions are temperate and well suited to the purposes intended, permitting of work all the year around. The location is also such as to afford unusual facility for the development of aircraft and their accessories suited to work on land and water under nearly all conditions which must be met in service. This feature alone makes it very desirable from the point of view of both the War and Navy Departments, as the development of aircraft suited to operation from rough water is one of the most important problems requiring solution in both services.

The committee feels that if the activities of the War and Navy Departments and of this committee can thus be concentrated at or near one station the greatest good will result, and therefore recommends that in the legislation for the War and Navy Departments and for this committee everything that would tend toward the accomplishing of this concentrated effort be given the most careful consideration.

FOREIGN NEWS

FRANCE

The Lafayette Flying Corps, composed of American aviators and commanded by two French officers, Captain Georges Thenault and Lieutenant de Laage de Meux, has shot down thirty German airplanes, according to a recent semi-official communication. Sergeant Raoul Lufbery has accounted for six, Sub-Lieutenant Bert Hall for three and others for one each. The late Sergeant Norman Prince shot down two and the late Sergeant Kiffen Rockwell two.

Speaking of Sergeant Rockwell, who had the honor of bringing down the first victim of the American squadron, Captain Thenault said: "Rockwell scarcely gave his helper time to fill the gasolene reservoir between flights. He was always where the German machines were thickest. Over Vaux and Douamont (in the battle of Verdun) he forced many of them to land behind their own lines to escape him."

The Lafayette Corps appears from this communication to have participated in the severest battles of Verdun and the Somme, contributing largely to the security of French aviators by relentlessly pursuing German machines and mastering the air over the fields of battle, thus enabling the observation pilots to regulate the fire of the French artillery. It was the Lafayette Corps which escorted the squadron that bombarded the Mauser rifle works at Obendorf, in the course of which there were numerous engagements, three German machines being brought down.

Sergeant Lufbery, with six German machines to his credit, is now rated among the expert aerial fighters.

GERMANY

The official report of Germany, issued April 8th, says that 161 Allied aeroplanes were lost in the month of March. The report follows:

"Our opponents, including Americans who were in the French aerial service long prior to the American declaration of war, lost in the month of March, in the west, east and the Balkans, 161 aeroplanes and 19 captive balloons by our attacks and anti-aircraft devices.

"Of these, 143 aeroplanes and nineteen balloons were shot down by fire from the ground. The German losses amounted to forty-five aeroplanes. No captive balloons were lost."

(According to this statement, the Allies lost only eighteen aeroplanes in air fights in March, while the Germans lost forty-five from all causes. The Allies have contended that the Germans seldom cross the battle line where their anti-aircraft guns could get at them, while the very number claimed by the German anti-aircraft guns—far more than claimed as shot down in air fights—shows the Allies must have been constantly above the German lines.)

GREAT BRITAIN

London, April 8.—A despatch to the *Daily Mail* says:

"The latest aeroplanes on both sides are of quite breathless speed. At one moment aeroplanes swish over you like a covey of birds. At another you see or hear no sign of their presence. A minute later faint mysterious sounds as of hammering on soft wood come from the heights and then one of the planes, either winged or too weak for combat, dives for harborage within its own lines.

"The fighting is now so quick and skilful that the slower, older machine has about as much chance as a sparrow against a hawk. All records were broken by one of the newest and fastest British machines which destroyed five of the enemy in one flight.

"The art of high diving has increased beyond telling. From 16,000 feet, where they are scarcely visible, or from the ambush of a cloud, planes come down like a plummet to bomb a train, to fire a balloon or to riddle a body of men with machine gun fire. Firing at small objects is daily practiced. So quickly do the divers come and go that men with loaded rifles on the very spot are often in their astonishment too slow to fire till the plane is well out of range. The German authorities complain bitterly that their infantry fail altogether to use their rifles on such occasions.

"The Germans have concentrated a number of their best airmen, just as earlier they concentrated a group of their best gunners, in which is known as a 'traveling circus' which gathers wherever they meditate an offensive. It is a mobile unit of expert fighters and photographers."

April 8, 1917, will be marked as being probably the day of the most furious aerial activity of the great war, and a day that established the superiority—temporarily at least—of the British airmen over those of the Central Powers. The full report follows:

With the British Armies in France

April 8, 1917.—Under a blue Easter sky, beflecked only here and there with bits of filmy white cloud, British aviators by the hundreds continued today their work of re-establishing beyond all question of doubt their supremacy in the air. They carried the fighting wholly into the enemy territory, sought out their aerodromes, military headquarters, ammunition dumps and concentration camps and challenged the Germans in every possible manner to come up and fight.

50 Miles Behind German Lines

In one instance the British flyers penetrated fifty miles behind the German lines. They fairly flew circles about a numerically superior enemy squadron which sought to intercept them.

To the laymen the weather seemed ideal for flying, but the airmen were inclined to complain because some of the woolly patches of cloud had enabled several hard-pressed German aviators to take refuge in their mist and escape immediate punishment.

"Give us three or four cloudless days and we will hit the Boche airmen such a blow that they won't be able to recover all summer," said an enthusiastic wing subaltern today.

The loss of twenty-eight machines in two days' bombing, fighting, photographing and observing is counted by the airmen as a small price to pay for the work accomplished, considering the number of machines engaged, coupled also with the fact that all these operations were within the German lines.

Against the loss of the British machines must be placed fifteen German aeroplanes, actually seen to crash down and thirty-one driven down damaged, most of which are believed to have been destroyed. The British will not officially announce a hostile machine destroyed unless two or more of their flyers actually see the falling plane ablaze or watch it crash into a hopeless mass of wreckage.

When flyers are engaged in fighting the formation is twenty or more machines, and when one begins to go down there is seldom time to watch the completion of its earthward journey. Under such conditions a hostile machine is not counted in the total enemy casualties. However, the British Flying Corps is absolutely unperturbed when its losses exceed those of the enemy. The men philosophically regard this as the penalty necessarily entailed in maintaining the offensive. Technically, the Germans seldom have a machine "missing," for with the fighting going on almost entirely on their side of the line all their machines driven down can be accounted for.

There is no comparison with the amount of work done by the British and German machines. To airmen maintenance of supremacy means ability to ascend daily and accomplish whatever aerial work is desired. Although the Germans have been more active in recent weeks, they have never interfered at any time seriously with this work. In bad weather, in which the British are unable to harass them, the Germans generally start prying over the British lines. Two days of fighting generally discourages them, however, to such an extent that the British believe a solid week of fighting weather will disarrange their flying plans for months to come.

The British have a great preponderance of machines, and at least thirty of these probably go over the German lines against one hostile machine flying on this side of the trenches. This ratio of activity within the enemy territory must always be set against the ratio of losses. The maintenance of a great number of machines enables the British to carry on a preponderance of artillery fire, directing their shots, not by hazard or "off the map," but under the actual eyes of the aeroplanes.

The constant aggressiveness of the British Flying Corps and the willingness of the splendid young pilots and observers to take every manner of risk means information for and protection of the army on the ground to an extent which they regard as amply repaying their sacrifices. Under their guidance on this Easter Day the British guns were roaring all along the far-reaching battle lines. It was a brilliant day for warfare as well as air fighting.

Such a day develops incidents beyond measure. Planes could be seen darting in and out of fleecy cloud banks, glinting at times like bits of silver in the sunshine and flashing away with the speed of a sunbeam itself. The distant patter of machine guns often told of fighting behind a cloud screen or at such a height that the machines were lost to view.

The task of suppressing German airmen is greater today than it was a year ago, but the British have set about to accomplish it with all possible speed.

JAPAN

The following reports are from *The Far Eastern Review*:

Japan Buys Aero Motors for Russia

Through the New York office of Mitsui & Co., the Russian Government has placed a huge order for aeroplane motors. These motors are being built by the Hall-Scott Motor Company in Berkeley, California. M. Yasumoto, a young Japanese engineer attached to the New York office of the Mitsui company, quietly went to San Francisco several weeks ago, tested the Hall-Scott motors, gave them a technical verdict, and is now supervising their construction at the rate of about two a day.

It is understood that the Russian Government is paying approximately $1,500 apiece for the engines and that the contract totals several hundred thousand dollars. The motors are shipped as fast as they are completed, the planes being built in Russia.

Yasumoto admitted that the contract was a large one, but refused to give the exact amount. It was learned that the placing of the order followed an unsuccessful attempt of the United States Government to procure a 400 horsepower motor for six huge, double engine planes. Silas Christofferson and other aeroplane builders were consulted in this quest but none could deliver the motor.

Japanese Aviators in China

Four Japanese aviators are now engaged to instruct the Chinese to fly at Tsingtao. They are aviators Sakamoto, Hoshino, Kumagi and Tachibana. Of the four, Sakamoto and Hoshino are wearing the uniform of major general and the other two that of colonel.

Every day they are giving instructions to the Chinese students, but as the aeroplanes they brought from Japan are not set up yet, they are only teaching their students the primary construction of aeroplanes.

Two aeroplanes are at the aviation field ready to be set up, and it is expected that the three machines of Mr. Y. Ozaki will soon reach

Japan's Aviation Programme

Japanese Military Aeronautics Investigation Commission which succeeded in the construction of aeroplane-destroyers and armored aeroplanes has under scheme the construction of a huge aeroplane with accommodation for a crew of eight. Another plan for the construction of an armored airship together with the establishment of the Military Aerodrome No. 2 is also under way. The armored airship will be modeled after Zeppelin airships with a length of 130 feet and a capacity of 20,000 cubic metres for its balloon, and will be equipped with four 300 h.p. motors capable of continuing an aerial cruise for thirty hours at a speed of 20 metres per second, with a crew of twenty and 200 *kuan* (1,666 pounds) of explosive. The new airship is to possess double the fighting power of the *Yuhi*. As previously reported, the new aerodrome is to be laid out in Kagamigahara (Gifu Prefecture). A hangar and an aircraft building yard will be reared. The surveys of the proposed site have already been finished. Owing to the financial consideration, the completion of the whole work in the coming fiscal year is thought doubtful.

Power Driven Paper Models

Mr. H. Major, an enthusiast on paper models, is responsible for the following report:

"Small paper aeroplanes, complete with rubber motor, 5-inch carved propeller, etc., turning the scale at a quarter of an ounce, are able to travel with perfect stability and certainty distances up to 300 feet in a straight line.

"During the past three and a half years I have constructed well over one hundred of these small scale models, meeting with such success that, upon occasion, I have been surprised myself by the performances of a new type. Indeed, I have no hesitation in saying that far more may be learned by an amateur of the essential conditions of flight by the use of these models than by the construction of a limited number of larger machines, the analysis of which is necessarily more complicated. An exhaustive study of the whole principle of aerostatics may be undertaken with the practical certainty of the deductions made being accurate in a high degree.

"There is no type of aeroplane existing of which it is impossible to make a small scale model with success. Tractor biplanes, propeller biplanes, with the screw revolving within the compass of the outrigger, and even scale copies of the old type Maurice Farman (here the tail booms are set farther apart so as to allow the use of a larger propeller), may be built to cover distances in proportion to the speed and design.

"Naturally an amount of time must be spent in perfecting details and adding refinements. For instance, it took me three months to design a really efficient propeller bearing, but then that bearing was standardized, and I have used no other pattern for three years. Also, a piece of folded paper is not an efficient, or even a strong, substitute for cross-braced interplane struts, and the use of such would radically affect the design of any model. It must be emphasized, however, that the greatest care must be taken in designing the model.

"The propeller, as an example, should be carefully carved so as to comply with the laws appertaining thereto. Do not when making a highspeed model fit it with swept-back wings under the impression that you are decreasing head resistance. This only serves to slow the aeroplane. It would be interesting to hear some correspondent's views upon this subject. The following few notes may be of assistance:

"In designing the first model choose a tractor monoplane.

"See that the wings have a good upward dihedral angle.

"Fit a screw of ample size.

"See that you allow sufficient stabilizing surface in the rear.

"The tail should be placed the greatest distance possible in the rear of the wings, and in most cases set at a slight negative angle.

"Do not use cardboard or drawing paper anywhere in the construction of the model. A hard bank paper is best with a smooth surface. Substance about 18 to 20 pounds demy.

"Make use of an adequate camber in the planes. A good all-round form is the following: Strike an arc two-thirds of the length of the required chord, and complete the line at a tangent. Vary the radius of the arc in proportion to the camber required.

"Construct the wings scientifically. One form is to use one thickness of paper, overlapping the leading and trailing edges, and then glue these down over two very thin can spars.

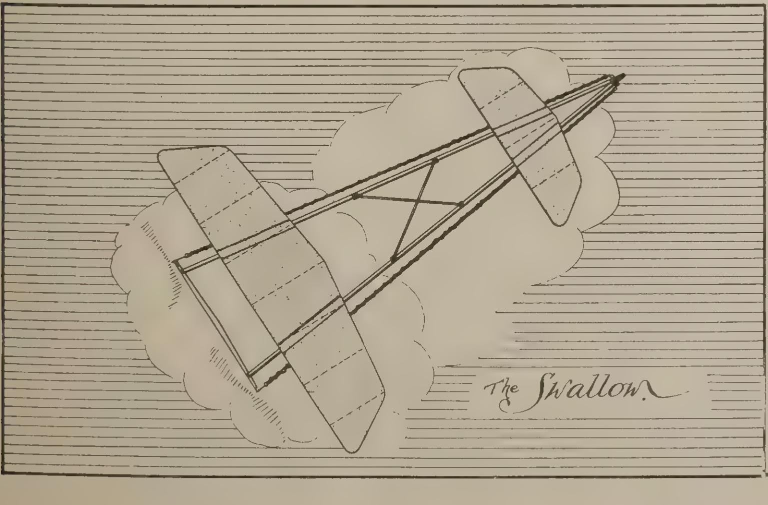
"Do not use gum or paste of any description. An adhesive such as seccotine is the most satisfactory.

"I may mention in conclusion that it is not unusual for these miniature aeroplanes to attain a height of 20 to 30 feet, and special looping models may be constructed with success."

Notice

Information has just come to hand that a new Model Club has been formed in Baltimore, and will operate under the name of the Broadway Model Aero Club.

We would suggest that all model flyers in the vicinity of Baltimore, desirous of furthering the sport, get in touch with the secretary, 927 No. Broadway, Baltimore, Maryland.



The Swallow—Drawn by Mr. Harry G. Schultz, representative of the Standard type pusher, rubber strand driven racing type model which has played such an important part in the history of model aeronautics and which is gradually being replaced by the more efficient scale type model. For a complete description see Volume III, No. 12.

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested

The Solar Seven

Invented and vouched for by the inventers of the Odor-Engine, and the Accordion-Plane. Registered in the Siamese Patent office. Fully protected in the United States by the Pinkerton Detective Agency. Price on application. Note: those buying in quantities will be charged a higher price, for if they can afford to buy a lot at once, they can afford to pay a good price for them. Because of the grave crisis which has been confronting our nation we have held back the announcement of this, our latest and greatest, invention. We thought for a while that there was a possibility of the Government buying the invention, and paying us a few million dollars for it, but since they have shown no signs of doing so, we present the description in this issue. We would have drawings but the artist who usually draws for us refused absolutely to do the job. He wanted more money, and we offered to pay him just what he was worth, but he said how did we expect him to live on that, and resigned in disgust. So we ask our readers to please use their imaginations, and imagine the completed engine in all its pristine glory.

Reel One

The Solar Seven, as may be surmised from the name, acts upon an entirely different principle. (So far our principal is limited, but we expect soon to sell stock). As the old Romans used to exclaim when viewing something marvelous in the way of inventions, *‘ab usque tandem, in fortitier derogatory.”* We are quite sure that if one of the old Romans could see our engine, he would make an even more rash exclamation. Notwithstanding.

The Solar Seven acts upon the principle that when the sun shines, it gives forth light, which light is dispersed in radially cogniscent segments, which segments may be said to be equal, each to each, in a ratio of five to one, with a remainder of $4.62 for error. Of course, we realize that this is directly opposed to Pascal's Law of Primo Geniture, but on the other hand, Pascal knew absolutely nothing about the law of obtaining money under false pretenses. Therefore, while acknowledging his many contributions to science and literature, we must state that we are starting out on new and unexplored fields, and we shall be governed by nothing except the laws of New York State, and the condition of our treasury. We have adopted for our business slogan the old saying of the Mosaic, —or Archaic—Cliff Dwellers; "When the Principle is different, the fulfillment thereof is transitory."

Reel Two

The sun sends forth light, and being careless, does not watch it to see where it goes. We take advantage of this carelessness, and use the light for the sole power of propulsion in our engine. We have a reflector which catches the rays of light, and send them in two directions. The first bunch of rays is directed toward a glass box which contains ice. The light melts the ice and it trickles down a pipe into a retainer, in the form of water. Once in the retainer, the other rays of light strike it, and it boils. Now we know by our chemistry that when water boils it expands and travels upward in the form of steam. Now we lead the steam through a turbine, which turns the propeller of the aeroplane! Simple? Absolutely! (The idea is meant, not the inventor).

Reel Three

Now the question goes up as to what we will do when our ice gives out. There is where we are clever! After the water, —that is the steam—has passed through the turbine, and forced the aeroplane ahead we lead it to a refrigerator. Now we have an auxiliary fan on the upper plane, which is driven by the air when the machine moves through the air. This fan drives another fan, which forces a stream of cold air directly on the refrigerator. The water in the refrigerator becomes chilled, and freezes. We know that at the moment of freezing water expands with an irresistible force. So the water expands, and releases a trip, which lets an axe fall on the ice, breaking it up, as soon as it is formed. Now the axe bounds back from the impact of the ice, and in bounding turns a small paddle wheel, which sweeps the ice back into the original glass box, where the cycle of operation starts all over again.

Reel Four

Now follows the most important point of all. Our machine, in action, weighs absolutely nothing! *Absolutely nothing!* "But why?" you ask impatiently.

"Listen," we return.

When the motor runs it turns another fan, and this fan has a lifting effect. The faster this engine runs, the faster the fan must go, and the more the entire machine must be lifted. In fact in a private test, conducted under the auspices of the State Board of the Absent Minded, it was found that when the machine goes at full speed, the weight of the engine must be reckoned in a minus quantity! With this solemn thought we leave our readers to gasp in admiration, and compose hymns in honor of the inventors of this, the greatest, grandest, and most garrulous invention ever conceived by the brain of mortal man. And when millions of our machines are in daily operation, just let it be said of us that we ever strove to improve the quality of our product, without losing any profit by it. We give our invention to the world. Whoever wishes to use it may do so without asking permission. (The royalty fee is one thousand dollars a machine).

WELL, HOW'S OUR YOUNG AVIATOR TO-DAY, EH?
FINE UNK! I WAS HIGHLY HONORED TO-DAY, I WAS!
TH' HEAD OF TH' AVIATION SQUAD CAME TO ME AN' SAYS "WE'VE JUST INVENTED A NEW MONOPLANE SOMETHING RADICALLY DIFFERENT! OF COURSE WE DON'T KNOW HOW SUCCESSFUL IT'S GOIN' TO BE —
— IN FACT WE DON'T KNOW WHETHER IT'LL EVEN FLY! THAT'S WHAT WE'VE GOTTA FIND OUT, SO WE'VE PICKED YOU TO TAKE IT UP AN' FIND OUT"
NOW, AIN'T THAT QUITE AN HONOR FOR ME?
OH SURE, SURE, QUITE AN HONOR! BUT I'D MAKE 'EM FURNISH TH' FLOWERS AN' MUSIC TOO!
POP—

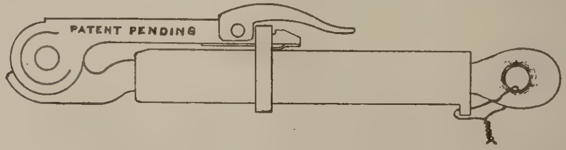
The Bellanca Turnbuckle
A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

Quotations and deliveries on request.

Burgess Training Hydroairplane

Among the many models of Airplanes, Seaplanes and Flying Boats produced by this company the new "U" type Hydroairplane meets a very pressing need—an efficient, well-balanced flying machine of conventional type and low power for militia training purposes.

The Massachusetts Naval Militia has the first one now in service.

Standard Deperdussin control in duplicate; Curtiss OXX-2 motor; simple float; light, sturdy construction; large speed range (forty to sixty-eight miles per hour); are characteristics necessary to the hard service required for training purposes.

Hydroplanes and pontoons designed and manufactured for airplanes of every type, including Curtiss, Sturtevant and other makers.

Designers and constructors for the U. S. Army and Navy and British Admiralty.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

AVIATION TRAINING

THE CURTISS School of Aviation will give training this winter, in Florida, to those civilians who may be accepted by the Aviation Section, U. S. A., upon their having made application for enlistment in the Aviation Reserve Corps. Applicants must be between twenty-one and twenty-seven years of age, possess good health, character and college education or equivalent. Tuition will be paid by the Government.

Duesenberg Motors

Announcement!

Duesenberg Motors Corporation has been organized to manufacture Aeroplane, Marine and Automobile Motors for those who can afford and demand the best.

EACH of the three types of motors will be built on the same general design, differing only enough to adapt them to their individual requirements. The Duesenberg Design has proven itself in actual service for a number of years.

> Duesenberg Motors are installed in Seaplanes now in the Service of the United States Navy.
>
> Duesenberg Motors were installed in the first motor boat to make a mile-a-minute speed.
>
> Duesenberg Motors were installed in the boat that won the Displacement Runabout Classic at the Miami Regatta this year.
>
> More than 60% of all racing cars on American Speedways in 1916 were equipt with Duesenberg Motors.

The Duesenberg Aeroplane Motor, a sixteen valve, four cylinder, 125 H. P. engine, typifies the evolution of the Duesenberg Design which has passed through the severe test of automobile and motor boat racing. It now occupies a dominant position in the field of internal combustion engine design.

The racing experience has refined this design to a hitherto unattained degree. It has made it possible to build an engine developing 1 H. P. for every 3.5 cubic inches piston displacement. Furthermore, this motor only weighs 3.5 lbs. to the H. P. and is probably the most compact aeroplane engine of its power in existence.

Duesenberg Aeroplane Motors have proven themselves in actual service. The United States Navy is using them in the Gallaudet Seaplanes. The Lanzius Changeable Angle of Incidence Airplanes also use this powerful motor as standard equipment.

A very interesting bulletin has been prepared on this Aeroplane Motor in which complete data is given in conjunction with full illustrations. Write or telephone for a copy to-day.

$120,000,000 FOR AERONAUTICS

APPROXIMATELY $120,000,000 is to be spent in army and navy aeronautics. The army "war budget" sent to Congress includes an estimate of $54,000,000 for aeronautics and $6,000,000 additional for personnel, etc., for the Army Air Service. The estimate for naval aeronautics is similar to the army's.

The National Advisory Committee on aeronautics advises a plan to train 2,400 aviators in the first year of the war, which ends April 1st, 1918. At least three thousand aeroplanes are to be ordered to carry out this plan.

High ranking officers from the French and British air services are being "loaned" to the United States and will assist the army and naval authorities in organizing our air services.

AMERICAN AEROPLANES ARE EQUAL TO THE BEST EUROPEAN PRODUCTS OFFICIAL REPORT STATES

THAT type for type American aeroplanes are equal to the best European products, and that American fighting aeroplanes have a factor of safety of six, whereas European machines have only a factor of safety of three—are facts brought out in the official report of an investigation made by the Advisory Committee on Aeronautics, of which Mr. Alan R. Hawley, the president of the Aero Club of America is chairman, and which is cooperating with Rear Admiral Nathaniel R. Usher, the Commandant of the Third Naval District, in the organization of the Naval Reserve Forces.

The results of this investigation form part of a detailed plan dealing with the aerial defenses needed for the Third Naval District, which extends from New London to Barnegat, particularly the aerial protection of shipping and the employment of aircraft for submarine hunting. This plan is withheld from publication for obvious reasons, but the results of the investigation is made public. It reads as follows:

Report on the Efficiency of American Aeroplanes

"Regarding the efficiency of American aeroplanes, our Committee has investigated the subject and has found that, type for type, American manufacturers supply aeroplanes equal to the very best European products. An investigation of statements of people who, on their arrival to this country from Europe, state that American aeroplanes are not used at the front in Europe has brought out the fact that the aeroplanes ordered in this country so far with the exception of our large seaplanes, which are superior to any European product, have only been the training type. A further investigation has shown that the reason why only the training type of aeroplane have been ordered in this country by the Allies is that the limited production in this country in the past two years did not permit deliveries of thousands of aeroplanes and it would have been most inefficient to send to the front a few hundred aeroplanes of a type for which spare parts were not available. This inability on the part of American constructors to deliver aeroplanes by the thousand at the time when the Allies needed the aeroplanes most made it necessary for the different countries to create their own sources of supplies for the bulk of the aeroplanes needed by them. The complaints from the representatives of different countries which have ordered aeroplanes in the United States are entirely of our limited output. They state that they could use thousands of additional aeroplanes of the training type—as well as of the remarkably large seaplanes which are not obtainable elsewhere outside of the United States.

"These facts are substantiated by the fact that additional orders have been placed continuously in this country for aeroplanes and aero motors.

"The Committee's investigation shows that all the reports regarding the alleged inefficiency of American aeroplanes and motors are based on the fact that close to two years ago, when it was almost impossible to get the suitable metals for crankshafts, a shipment of American motors proved to be unsatisfactory and the motors had to be reconstructed in England. But the investigation also shows that the Allies had the same trouble at the time with British and French products. These facts were brought out by the recent investigation of the Royal Flying Corps of Great Britain.

Investigation of the Efficiency of American Fighting Aeroplanes

"Our investigation shows that the statements made recently, to the effect that American fighting aeroplanes do not have the speed and climbing ability of foreign fighting machines, is based on the fact that in America we demand a factor of safety of six, whereas foreign machines only have a factor of safety of three. Likewise, whereas foreign countries accept machines that land at a speed of close to 100 miles an hour, in the United States we expect our fast aeroplanes to land at a speed not exceeding 60 miles an hour. Considering that we have a factor of safety twice as large as the foreign machines and that we have a landing speed not exceeding 60 miles an hour, our fighting machines compare favorably with the foreign machines in speed. We get a speed of approximately 130 miles from our machines while the European machines, with the lower factor of safety and greater landing speed, get only about ten miles more."

Almost simultaneously with the publication of the above report there were published in various publications information from European sources which shows that this report is based on actual knowledge of inside conditions existing in Europe as well as in the United States. The account of the death of Norman Prince, at the end of the raid on the Mauser works, for instance, shows that the Nieuport fighting machines only carry fuel for two hours, and land at a speed of about 100 miles an hour. The factor of safety of a Nieuport is supposed to be less than 3, it having been cut down to increase the speed. This was logical, because the factor of safety is not of any use if the aviator risks being shot by the faster enemy aviator.

But who will dare to propose to the United States Army and Navy authorities to cut down the factor of safety to 3? If a death should follow the cutting down of the factor of safety the person who proposed it would feel that he assumed more responsibility than one can assume so long as we do not have to fight enemy aircraft off the American skies.

It will, of course, be different when we decide to send aviators to Europe. Then they will have to be trained on the fastest machines obtainable. In the meantime they can be trained on machines having a speed of up to 120 miles an hour. Thorough training on these, and training on aerial gunnery, will fit them for the intensive training to be taken before actually going to the fronts.

There are at present two Nieuport machines in the United States, purchased by the U. S. Government. We shall await their tests with interest. The tests of the Vickers speedster at Governor's Island have been interesting, but the average of breakage on landing has been extremely large, so far.

The statements made in the British Parliament also give evidence that some of the claims made for foreign machines are not borne out by facts. On March 13, for instance, during a long discussion of certain conditions existing in the Royal Flying Corps there was brought out that a speed of 117 miles an hour, was considered extraordinary and members of Parliament demanded an inquiry to find out why the military authorities had not ordered machines of that type.

In connection with a statement made by the British Under Secretary of State for War Macpherson, regarding the average casualties per week in the Royal Air Services during the preceding six weeks, Mr. Billing, a member of Parliament, made the following statement:

"I would like to suggest to the honorable gentlemen on the Front Bench that the majority of these fatalities can be directly attributed to machines being sent up in which I said twelve months ago that our men were being murdered. I stand here twelve months later, and I say even on this very day that men are being murdered by being sent up in these machines. Our men are today being sent up in BE2 gun spotting. These machines are utterly incapable, armed and equipped as they are, of rising over 5,000 feet. They are sent up with two 20 lb. bombs, and two guns fitted on them. The guns, however, are not adequately fitted for fighting. These machines are sent six miles out into the enemy's lines. Only recently I had two or three cases brought to my notice of men sent out gun-spotting, and with them they had two of what are called chasing machines, but they lost the chasing machines, they stopped over the lines at the mercy of the German airmen, and they were eventually shot down. Quite recently, two fell in flames in our own lines. We have machines faster than any of the Germans have at the front at the present time."

We know, of course, that the Spad is a good machine. But we also know that it is also limited to carrying fuel for two hours, landing at a speed of not less than 80 miles an hour, and has a factor of safety of about 3. We feel certain that American manufacturers can build machines having the speed of the Spad if the other requirements are to be as obtained in the Spad.

The Advisory Committee on Aeronautics, cooperating with the Commandant of the Third Naval District in the organization of the Naval Reserve Forces consists of:

Alan R. Hawley, Chairman; Captain Robert A. Bartlett, Howard S. Borden, August Belmont, W. Earl Dodge, F. Trubee Davison, William Dubilier, F. C. G. Eden, Rear Admiral Bradley A. Fiske, Frank Guggenheim, Congressman Murray Hulbert, of New York; John Hays Hammond, Jr.; J. F. Knapp, Rear Admiral William N. Little, Frank N. Leavitt, Congressman F. H. La Guardia, of New York; Robert A. Lovett, Augustus Post, Rear Admiral Robert E. Peary, Harold Irving Pratt, Lawrence B. Sperry, Lewis S. Thompson, Eugene S. Willard, Evert Janson Wendell, Charles Elliott Warren, Schuyler Skaats Wheeler, Henry Woodhouse.

REPORT ON AERIAL DEFENSES NEEDED FOR FIFTEEN NAVAL DISTRICTS MADE CONGRESSIONAL DOCUMENT

The remarkable report, explaining in detail the aerial defenses needed for the fifteen naval districts, which was drawn by the Advisory Committee on Aeronautics co-operating with Rear Admiral Usher, the Commandant of the Third Naval District, has been made a Congressional document and was printed in the *Congressional Record* of April 13.

Congressman Murray Hulbert in presenting the report to Congress paid a much deserved compliment to the Aero Club of America and the patriotic men who have given their time and funds to developing our aerial defenses.

By stating the coast aerial needs of the naval districts this report gives a valuable base for the aeronautic industry and those interested in aerial preparedness to work on.

Copies of the report, which covers eight printed pages, can be had by applying to AERIAL AGE, 280 Madison avenue, New York.

The Advisory Committee that prepared this report consists of Alan R. Hawley, chairman; August Belmont, Howard S. Borden, W. Earl Dodge, Rear Admiral Bradley A. Fiske, retired; Rear Admiral Robert E. Peary, retired; Frank Guggenheim, F. Trubee Davison, Capt. Robert A. Bartlett, Congressman Murray Hulbert, Congressman F. H. La Guardia, Lawrence B. Sperry, William Dubilier, John Hays Hammond, Jr.; J. F. Knapp, Rear Admiral William N. Little, retired; F. C. G. Eden, Robert A. Lovett, Augustus Post, Harold Irving Pratt, Lewis S. Thompson, Eugene S. Willard, Evert Jansen Wendell, Charles Elliott Warren, Schuyler Skaats Wheeler, Rodman Wanamaker and Henry Woodhouse.

This committee has actually taken steps to establish ten seaplane stations in the Third Naval District, and is co-operating in forming units of the Aerial Coast Patrol. About 200 men connected with different units are under training or about to take up their training.

Eyes Above.

[Editorial in the *N. Y. Globe*.]

British eyes searched the German armies last Saturday (April 7) with a thoroughness that must have chilled any hopes General von Hindenburg has cherished of a fresh surprise, whether backward or forward. His "trimphant" retreat was ascribed to his ability to put the enemy's eye out. The fliers that brought back seventeen hundred photographs of his positions and dropped eight tons of dynamite where explosions are least wanted should enable Generals Haig and Nivelle to forestall his next move, if they want to do so.

How important this extraordinary aerial reconnaissance actually was in observations made and German aeroplanes destroyed we have no present means of estimating. The operations of the men who do their work on and in the earth may soon give us a clue to the practical value of the information obtained. No knowledge of confidential reports is needed, however, to disclose the enormous advantage possessed by armies equipped for such work. The most untutored civilian can judge something of the difference between total ignorance of what your enemy is doing and such complete knowledge of his dispositions as may be gained by swarms of peering airmen provided with tell-tale cameras.

Most American military men know that we have thus far done little or nothing to qualify us for jobs of this kind, though we were the first to get men into the air for practical purposes. If we are to raise a real army we must not long delay what has to be done for the air service.

For a Department of Aviation.

[Editorial in *Philadelphia Inquirer*.]

Senator-elect Caldwell, of New York, announces his intention of introducing a bill at the forthcoming session of Congress creating a Department of Aviation, to be headed by a new Cabinet officer, who shall take complete charge of the aviation service of the country.

The point may be made that there is no aviation service for the proposed Secretary of Aviation to take care of, but the answer is that the demand will soon create the supply. This suggested departure is in line with the campaign which has been so vigorously prosecuted by Admiral Peary for the last six months, and if carried out would help to put the air service of the Nation upon a substantial and respectable basis.

No important nation on earth is so poorly equipped in the matter of flying machines as the United States. Now that we are actually preparing for war, it becomes necessary to provide such equipment, and experts are of the opinion that it can be best done by the creation of a new department. Admiral Peary is confident that with the proper encouragement we can get the men and the machines. He feels that there are thousands of young men in this country who can be taught to handle an aeroplane as well as a chauffeur handles an automobile. With the men and the machines, a comprehensive aero coast defense system could be established along the seacoast. Finally, the Admiral believes that we would have an industry developed which would be to the air service what Krupp is to Germany and Bethlehem to the United States in their fields.

It is to be borne in mind always that this work of air preparedness is not merely for the present German danger, but for the future. We have been stimulated to activity in all lines of defense by the crisis which confronts us, but it must not be forgotten that we are building for the future as well as the present. We seem to have learned our lesson, but it will not be much good unless we look forward. By preparedness alone can we insure ourselves against the dangers of invasion.

The News of the Week

Willys-Overland to Build Curtiss Motors

Buffalo: The order under negotiation by the Curtiss Aeroplane & Motor Corporation with the Willys-Overland Company for 4,500 Curtiss motors for use in aeroplanes is indicative of tremendous volume of orders which this Government is placing and will place to fill its requirements for the air service.

It is further significant that the Willys plant is willing to turn its excess capacity over to construction of aeroplane motors through the medium of the Curtiss organization, which latter corporation will probably be the major factor in the equipping of the aerial departments of the army and navy.

For the last two years the Curtiss plant has been turning out large numbers of aeroplanes and motors for foreign governments. At present this company has about $12,000,000 worth of orders on its books exclusive of any Government orders placed during last week—production is at the rate of about $1,000,000 worth a month, but this output can speedily be increased.

Standard Aero Corporation Supplies Brazil With Hydros

New York: The Standard Aero Corporation of New York, in a communication to Aerial Age, announces that it has sold three twin-motored Model D-2 hydroplanes to the Republic of Brazil.

The purchase of these machines was made by Consul General H. C. de Martius Pinheiro of Brazil, upon recommendation by a Naval Commission consisting of Capt-Lieutenant Luiz A. Graca, and Lieutenants Raul Vianna Bandeira and Victor de Carvalho Silva. The latter two are experienced naval aviators while Capt.-Lieutenant Graca is an ordnance expert.

The three twin-motored hydro-aeroplanes are of the same type as those ordered by the United States Army for coast defence purposes, each being equipped with two Hall-Scott A-5 motors with a very complete service equipment consisting of aeronautical inplements, Sperry bomb sight and dropper, Sperry wireless equipment with a sending radius of 25 miles, Herbert and Huesgen aero cameras.

The Holsam Company, Inc., who were the agents for the order in this country, are remarkably well equipped for handling aeronautical lines in South America as they have had a large experience in the export of machinery and various mechanical appliances and are furnishing several of the South American Governments with vast quantities of supplies yearly.

Joseph P. Knapp Presents Seaplane Station

To facilitate the Aerial Coast Patrol for the Third Naval, Mr. Joseph P. Knapp, President, American Lithographic Company, and a director of the Metropolitan Life Insurance Company, presented to Rear Admiral Nathaniel R. Usher, the Commandant of the Third Naval District, a seaplane station, with hangars and receiving wireless station, located on his property at Mastic, on the south shore of Long Island. The offer was made through the Advisory Committee on Aeronautics, of which Mr. Alan R. Hawley, the President of the Aero Club of America, is the chairman; and recently a committee consisting of Messrs. Alan R. Hawley, Rear Admiral Bradley A. Fiske, Henry Woodhouse, Clinton Davis Backus, the organizer of Aerial Coast Patrol Unit No. 3, Warren S. Eaton, David Dunlap, W. Hogeson, Henry Melvin Frauenthal, and E. K. Jaquith, the aviator who recently flew from Atlantic City to Miami.

The committee, which was shown through the property by Messrs. J. P. Knapp, and his son, J. F. Knapp, found the station to be ideally located from a strategical standpoint, as it is half way between New York and Montauk Point, therefore making it possible for the seaplanes to undertake a patrol to almost any point along the coast of the Third Naval District.

The station having been found suitable for the purpose, it has been accepted by Admiral Usher, and the hangars for the seaplanes will be put up immediately, and one of the units of the Aerial Coast Patrol will take their training at the station.

Norma Bell with Norma Ball Bearing

Mr. Norma Bell, formerly sales engineer in the Automobile Division of the Lunkenheimer Company, Cincinnati, has joined the Norma Company of America—makers of "Norma" High-Precision Bearings—in a similar capacity.

Aero Club Presents Balloon

New York City.—Rear Admiral Usher of the Third Naval District last week accepted an offer from the Aero Club of America of an observation balloon, especially designed for anchorage from a ship from whence for many miles it could watch for submarines and other hostile vessels.

This will enable the Navy Department to begin the training of operators for observation balloons. At present the navy has only one aviation training station, which is at Pensacola, Fla., and this is being used exclusively for the training of fliers. The balloon is in course of completion by the Goodyear Tire and Rubber Company, at Akron, O. It is also making the observation balloon for the United States Army Reserves, the fund for which was raised by Mrs. Charles E van Rensselaer and others.

Another fund is now to be raised for the training of aviators for the National Aerial Coast Patrol of which Rear Admiral Peary, retired, is the head. The National Special Aid Society has appointed a committee to campaign for this fund. It is headed by Admiral Peary and Miss Ruth Law, and other members are Cosmo Hamilton, Mrs. Robert Oliphant, Mrs. Arthur Scribner, Miss Katherine Glidden, Mrs. William McAdoo, Mrs. Wilbur Matthews, Mrs. Henry A. Wise Wood, Mrs. George Stevenson, Mrs. Percy Stewart, Mrs. Frank Hagenmeyer and Mrs. C. L. Baldwin.

S. A. E. War Plans Ready

New York City.—The Society of Automotive Engineers has its plans well laid for co-operation with the national government on all matters of defense.

Some of the general activties of members of the S. A. E. in event of war will be: 1—To build engines for submarine chasers through affiliation with marine engineers; 2—To build aeronautical engines through affiliation with aeronautical engineers; 3—To build motor convoys and transports; 4—To man them if necessary. Thus the S. A. E. will serve the country on land, air and water.

War Talk by Ruth Law

New York City.—Miss Ruth Law told of her experiences on the western war front with the French Flying Corps at the opening of the tea garden, last week, at the show of the Society of Independent Artists in the Grand Central Palace.. From the opening and through the evening the garden was in joint charge of the Garden Club of America, represented by its President, Mrs. Charles Hoffman; Miss Katherine Dreier and others, and of the Aviation Committee of the National Special Aid Society, proceeds going to the Naval Aerial Coast Patrol.

There were talks also by Cosmo Hamilton, Henry A. Wise Wood and Rear Admiral Robert E. Peary, and moving pictures of the aero corps in action on the fighting front.

Estimated Output of Aeroplanes

Washington.—During the next year aeroplane manufacturers of the United States will be able to turn out for the army and navy 640 flying machines. The output at the end of two years is put at 2,000 machines, and at the end of three years at more than 6,000.

These figures are based on careful estimates made by army and civilian experts after a survey of the facilities and resources of the manufacturers.

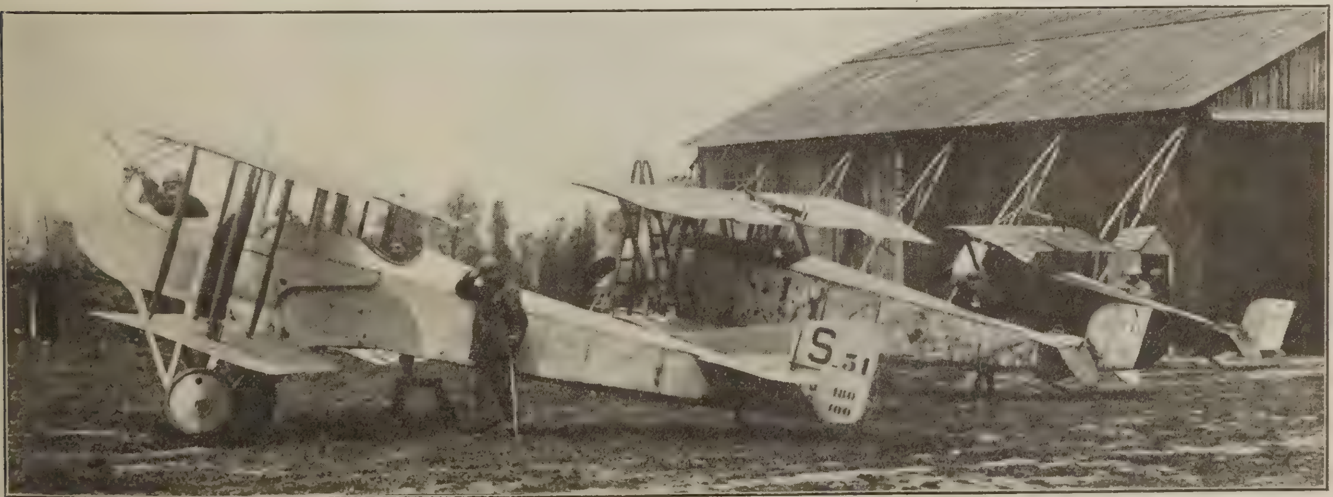
The army alone wants thousands of aeroplanes at once, but at present they are being turned out at the rate of about forty a month, with an increasing ratio.

Army Wants Thousands

The plans of the army alone for the next three years call for 3,700 machines by the end of the next fiscal year, 6,070 during the second year and 9,300 at the end of the third. These machines are of the school type for use in training flyers for the army. In addition, if it becomes necessary to send a force to Europe, the United States will require a large number of scouting machines, battleplanes and other types of aircraft used by the European belligerents.

The army now has less than 200 aeroplanes, whereas something like 10,000 young men and some young women have signified their desire to enter the aviation service. This branch of the army has been so exploited that officials are swamped with applications. Every private and army school is filled to capacity at present.

Would-be flyers are required to take a preliminary course of four months. This merely fits them to go ahead, but does not make seasoned flyers of them. The idea is to train there new squads of prospective flyers every year, giving each a course of four months.



The first picture of the French "Spad" tractor biplane (on the left of the illustration) that has been received in this country. Some of the unique details of this machine will be discussed in our next issue. The other machines in the picture are a Nieuport biplane and Nieuport monoplane scout

Pacific Aero Club News

San Francisco.—The eighth annual meeting of the Pacific Aero Club will be held in San Francisco on May 8, when the annual election of officers will occur and business of great importance will be transacted. Active participation on the national defense propaganda and the newly awakened interest throughout the country in aviation has resulted in the greatest activity in the Aero Club. The services of the club, which includes in its membership some of the ablest flyers and best technical men in the aviation industry, were offered to Secretary of War Baker and this offer was gratefully accepted by him on behalf of the United States Government.

The club is closely affiliated with the National Aerial Coast Patrol Commission at Washington, D. C., and with the Aero Club of America, of New York City, which is doing similar work on the Atlantic coast. Plans are now being formulated for the acquisition of a flying field down the peninsula where a clubhouse will be erected for the use of the members.

The newly aroused activities and the increasing number of applications for membership have resulted in a reorganization of the scale of membership with largely increased initiation fees for the various classes. All members in good standing prior to this action being taken are to be known as charter members and their dues will remain the same. This ruling also applies to those members who are engaged in the government service and to those who are active flyers or engaged in the aviation industry.

At the recent meeting in the Palace Hotel, President James C. Irvine, who has attended the Pan-American Aeronautical Exposition in the Grand Central Palace at New York City, as delegate from the Aero Club, made his report in which he described the great interest taken in the exhibits by all classes of people who thronged the building throughout the week of the exposition. Mr. Hall, of the Aerial Reserve Corps, addressed the club, giving a detailed account of the work being done. Vice-President Guy T. Slaughter responded to his remarks and announced that the reserve corps would receive all possible assistance from the club. The rapid movement of events is expected to develop a condition where the club will be in a position to take an important part in the coast defense movement which is now coming to a head.

Yale Flyers up at 4:30

West Palm Beach, Fla.—The thirty Yale students studying aviation for coast defence work after two weeks breaking in are being hardened for active service.

Lieutenant Trubee Davison, the ranking officer, son of H. P. Davison, gave instructions that the boys be called at 4:30 a. m. daily, and at 5:30 they are at the hangars hard at work. They have a training table with the same dieting given college athletes. They expect to stay here until June 15.

Boxer Volunteers for Aviation

New York City.—While nearly all the prominent boxers in America have announced their willingness to serve Uncle Sam, and doubtless will do so, Eddie Nugent, a welter boxer of Nutley, N. J., has the honor of being the first pugilist to enlist and begin actual service. Nugent left his home last week for Pensacola, Fla., where he will take up his duties as a member of th United States Aviation Corps.

Nugent is one of two out of eighty applicants at the Nutley recruiting station who passed the rigid examinations for admission to the country's air fighting service. He is 21.

Capitalization of Aeroplane Companies

Capital of new corporations for manufacture of aeroplanes and war munitions organized in March amounted to $2,825,000, compared with $2,450,000 in February. In 1915 amount was $3,835,000; in 1916, $50,192,000, and in the first three months of 1917, $6,825,000, a total of $140,852,000.

Export of Aeroplanes

The Editors of AERIAL AGE wish to announce that until further notice all reports of exports of aeroplanes and parts have been withheld by the customs authorities.

Organize Kentucky Aeroplane Corps

Louisville, Ky.—Organization of an aviation corps which later will offer its services to the Government was planned last week in this city. The preliminary boosting of the move is being done by Cliff Hogan and others interested in motor mechanics.

It is understood the company will elect a man of military experience as captain and give the noncommissioned offices to those most expert in handling aeroplanes and those experienced in building and repairing them.

Quentin Roosevelt in Aviation Corps

Montreal, Can.—Quentin Roosevelt, son of Theodore Roosevelt, has joined the Canadian Aviation Corps to obtain instruction for service with an American army at the European front should such an expedition go abroad, it was announced to-day. If no American troops go to France, Mr. Roosevelt will serve with the Canadian air forces.

Starting Aero Reserve in Boston

Boston, Mass.—An aeronautical naval reserve, with units comprising four officers with the rank of ensign and twenty-four men rated as machinists, mechanics, radio operators, etc., is being organized in the First Naval District. For this both officers and men are needed. Most of the officers will be actual military aviators, and will have an ensign's commission. Qualifications for an ensign's commission are a college education, or its equivalent, and, in particular, a good knowledge of plane geometry, trigonometry and algebra. Any applicants for a commission should brush up their knowledge of these studies before applying. Professor Klemin of the Massachusetts Institute of Technology has consented to give a class of candidates a course of instructon, consisting of sixteen lectures, running over a period of eight weeks, and coming at 5 P. M. Mondays and Thursdays, beginning Monday, April 9.

A written examination will then be given. It is the intention to instruct in flying the men who show the greatest proficiency in the subjects taught. Announcements of further instruction are to follow, but no one not familiar with plane geometry, trigonometry and algebra is likely to derive much benefit from these lectures.

Candidates for an ensign's commission are requested to call at the office of Godfrey L. Cabot, aviation aide, U. S. N. R. F., First Naval District, Room 940, Old South Building, between 11 A. M. and 4 P. M., any week day. Candidates for other positions should call on Lieutenant G. D. Murray on the seventeenth floor of the Custom House.

It is understood that no one will receive an ensign's commission until he has passed his final tests as an expert military aviator.

The city of Rio de Janeiro, taken from a training machine of the Brazilian Naval Air Service, by Lieut. Victor de Silva, Lieut. Roul Bandeira piloting the machine

Simplex and G. V. for Aero Engines

New York.—Among well known plants likely to be called upon for aviation engine manufacture are Simplex, now a part of the Wright-Martin Company and the General Vehicle Company. The former is now in full production with the Hispano-Suiza engine for the Allies while the latter is just completing a British order for Gnome engines and is now making them on a United States order. The capacity of the two plants is fairly large, and being already in production there would be no delay whatever in greatly increasing the outputs. The General Vehicle Company is also tooled up for the production of 3-in. shells and is practically through with its foreign order.

Magnetos Available for Aviation Service

One thing for which the American governmment will not be in difficulties in the same way as the Allies were is in the matter of magnetos. Splitdorf, Zenith, Bosch, and other firms are well able to take care of the aviation need, in fact their capacity is so great that the maximum demands that could be made by the air service would hardly be felt. Makers of such specialties as ignition devices, ball or roller bearings, carbureters, etc., are unlikely to be affected very much.

Nineteen Princeton Men for Aviation Corps

Princeton, N. J.—Of the 166 undergraduates at Princeton University who have left the college for military service ninety-three have gone into the mosquito fleet, nineteen into aviation, thirty-five to the militia, two to the United States Navy, one to Annapolis, four to coast patrol work, one to the Signal Corps and ten to France for ambulance service.

Standard Parts Adds Western Spring

Cleveland, O.—Definite announcement of the purchase of the Western Spring & Axle Co. by the Standard Parts Co. has been announced by President Christian Girl of that company.

Mr. Girl stated that the acquisition of Western completes the original program for the parts organization, and that the Standard Parts Co. will now be developed and rounded out on the basis of the companies now represented.

These include the Perfection Spring Co., the Standard Welding Co., the Bock Bearing Co., Toledo, and the Western Spring & Axle Co., with plants in Canton, Wheeling, Cincinnati and Carthage, Ohio, St. Louis, Connersville, Ind., and Flint and Pontiac, Mich.

The Standard Parts Co. as now constituted will use 175,000 tons of steel annually and will employ from 8,000 to 9,000 men. Its increased buyer power, with a large volume of production and diversity of products including springs, axles, rims, tubing, bearings, heaters, etc. together with an advantageous distribution of plants is expected to permit of many economies.

Marine Corps Reserve B.

New York City.—The U. S. Marine Corps has issued a call to automobile owners who wish to serve their country by enlisting in what it terms the Marine Corps Reserve B. Citizens who are capable of performing special useful service in the Marine Corps in the defense and maintenance of naval utilities, are eligible for membership in this class.

For instance, owners and operators of automobiles, motor trucks, motorcycles, aeroplanes, and other craft suitable for purposes in defense and maintenance of naval utilities, may be enrolled in this class and contracts made with such owners to take over their vehicles and crafts in time of war or national emergency upon payment of an indemnity.

Form Society to Train Aviators

New York City, April 12.—Six women decided yesterday at a meeting in the home of Mrs. Henry Slayback, No. 375 Park Avenue, to form the Aerial Aid Society, to train twelve college men as operators of seaplanes for the Aerial Coast Patrol.

Th society's founders are Mrs. K. R. Fell, Mrs. Henry A. Wise Wood, Mrs. Charles Carscallen, Mrs. Charles Baker, Mrs. Charles Smithers and Mrs. Slayback. The twelve men to be trained will form a unit of the Aerial Coast Patrol, to be assigned wherever the Navy Department may wish.

Henry Woodhouse, member of the Board of Governors of the Aero Club of America, said at the meeting Great Britain had spent approximately $350,000,000 on her air service. He said all ships approaching or clearing at British ports are inspected and convoyed by aeroplanes, and he urged similar protection in this country.

Fisher Offers Aeroplanes to U. S.

Indianapolis, Ind.—Mr. Carl G. Fisher, who recently made a formal offer to the Army Aviation Department at Washington, D. C., of the use of the Indianapolis Motor Speedway as a training camp for aviators, has, in a telegram to the Department, also offered aeroplanes to the Department in addition and called attention to the fact that hundreds of automobile testers in Indianapolis would make the best possible material for aviators in time of war. The Aviation Department is anxious to accept the offer, but has postponed acceptance pending action by Congress on a bill to provide funds for the establishing of aviation training camps.

National Institute of Efficiency Interested in Aeronautics

A meeting of the Board of Governors of the National Institute of Efficiency was held at the Aero Club of America, 297 Madison Avenue, New York, on Wednesday, April 4, 1917, there being present Mr. Melvil Dewey, Mr. Henry Woodhouse, Mr. Richard B. Watrous, and Mr. Karl V. S. Howland. Those present acted as proxies for Mr. Henry A. Wise Wood, Mr. J. Horace McFarland, Rear Admiral Robert E. Peary, Mr. Conrad H. Syme, Mr. Herbert W. Rice and Mr. C. J. Mar.

Appropriate reference was made to the death of Mr. William B. Howland, and the following motion was passed: "Recognizing the great work done by the late William B. Howland as a personal exemplar of efficiency and as the founder of this Institute, the Board of Governors takes this occasion to express its profound regret at his death, and directs that the memorial announcement already sent to the members be spread upon the minutes."

On motion of Mr. Woodhouse, seconded by Mr. Watrous, Mr. Melvil Dewey was unanimously elected to fill the vacancy in the presidency.

On motion of Mr. Watrous, seconded by Mr. Dewey, Mr. Karl V. S. Howland was elected to fill the vacancy of the Board of Governors.

On motion of Mr. Dewey, it was unanimously voted to amend the by-laws so as to provide for the election of seven trustees who between meetings of the Board shall have power to act for the Board in any matter not in conflict with the by-laws or the direct vote of the Board, and that the following members of the Board be elected Trustees: Mr. Karl V. S. Howland (Executive Chairman), Mr. Henry Woodhouse, Mr. Richard B. Watrous, Dr. Henry S. Drinker, Mr. Raymond B. Price, Mr. John A. Stewart, and Mr. E. St. Elmo Lewis.

On motion of Mr. Woodhouse, seconded by Mr. Dewey, Mr. John A. Stewart was elected Chairman of a Committee on International Affairs, with power to appoint members of the Committee.

On motion of Mr. Dewey, it was unanimously voted to amend the by-laws so as to provide for raising the number of Governors to thirty.

On motion of Mr. Howland, it was voted that in view of the desire of the Institute to be of the greatest possible service as an organization in the national crisis the preparation is authorized of one or more special monographs dealing with various aspects of the United States' participation in the war. This monograph is to include a chapter on efficiency in military aeronautics to be written by Mr. Woodhouse.

The action of the Secretary in sending to the Vice President—Hon. Alton B. Parker—a telegram of sympathy in respect of the death of Mrs. Parker, and also arranging for the attendance of three delegates—Rear Admiral Robert E. Peary, Mr. Henry A. Wise Wood and Mr. Henry Woodhouse—to the annual meeting of the American Academy of Political and Social Science, was approved.

May Have Aeroplane Factory in Atlantic City

Atlantic City, N. J.—It is reported here that Glenn Curtiss will shortly come to this city. With his coming there is information that the local plant, engaged in construction of aircraft, is be enlarged and taken over by the Government. It is now in operation, the executive departments being headed by trained men, and the building occupied has sufficient floor space in which the capacity of the plant, now four per month, can be speeded up to thirty per month.

Beryl Kendrick, who is interested in the aeroplane factory, has been drafted by the University of Pennsylvania, and will be placed at the head as instructor of the institution's plan to establish an aircraft school and a corps of men, which will be placed at the serivce of the military authorities. With him in the plant, as partner, is Blaine Elkins, son of the late United States Senator Elkins, of West Virginia, who, while he makes Washington his home, has been residing at the Traymore. He has been giving attention to the inventions being tried out at the factory here under the supervision of Glenn Curtiss, who built all the engines used here and supplied the designs from which they had been constructed.

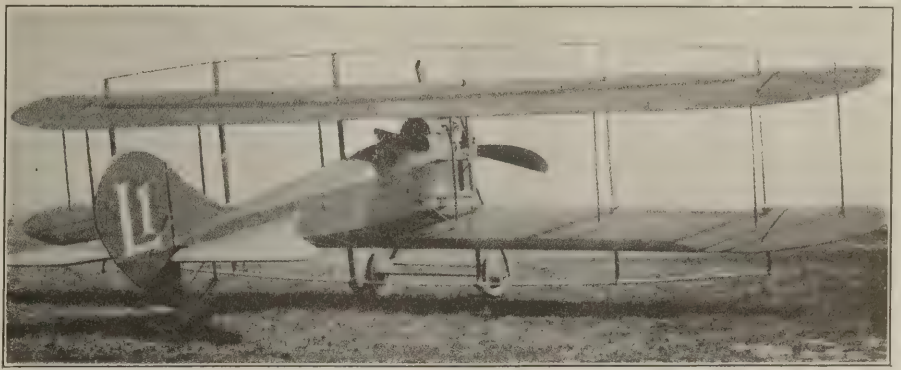
It is understood that the Government has had agents negotiating to lease the factory, and take it over in order to meet the rush order for hundreds of airships of the war types which the factory has been turning out.

Proffers Site for Aviation Field

Swedesboro, N. J.—Mayor Stone has made an appointment with representatives of the Aero Club of Pennsylvania to look at two or three sites in this vicinity, with a view of establishing a permanent aviation field. It is within a radius of 50 miles of Philadelphia. The borough council has taken up the matter, and there is every indication of success.

Champion Ready With Aviation Spark Plug

Flint, Mich.—The Champion Ignition Company, maker of AC spark plugs, now has ready for the market what it terms an aviation plug, but which is suitable for use on both aviation and racing motors.



The Model L-1 tractor biplane of the Lanzius Aircraft Co., with changeable angle of incidence, and equipped with a Duesenberg motor

Augustus Post Speaks Before Women's Club

New York City.—Mr. Augustus Post, of the Aero Club of America, last week addressed the members of the Brooklyn Women's Club, upon the subject of aeronautics.

Mr. Post urged Brooklyn women to send their sons into the aeronautic service. He said one aeroplane fighter was as valuable as a whole army corps, and that, although United States planes were inferior to foreign machines, they are being brought to a state of efficiency. He expressed satisfaction at the unfurling of the American colors by the Lafayette Aero Corps on the French front. He suggested that members of the Brooklyn Women's Club select proteges they desired to have trained in aero service and the Aero Club will train them.

Following Augustus Post's address on the aeronautic branch of the army and navy, in which training and preparation of this arm of the service were related, ex-Senator Towne declared that, in his opinion, the most important fact in connection with the talk was that almost every great instrument used in the war was of American invention. He mentioned the submarine, the aeroplane, ironclad battleships, armored trench tanks and the like. He pointed to these facts in illustrating his declaration that American genius will end the war.

May Locate Aircraft Factory in South

Richmond, Va.—With a view to locating a plant for the manufacture of military and commercial aircraft, C. M. Wanzer, of Ohio, is in the city relative to a site for the proposed factory. Business Manager Dabney, of the Richmond Chamber of Commerce, is giving Mr. Wanzer all the assistance possible.

It is said all the money necessary for the establishment of the plant has been subscribed, and a suitable site is now being looked for. Richmond, it is thought, will offer special advantages on account of climatic conditions and the location here of allied industries.

Army and Navy Orders

First Lieutenant Warren C. Woodward, Aviation Section, S. O. R. C., to active duty at Aviation Station, Memphis, Tenn. (April 7, War D.)

Each of the following officers is detailed in Aviation Section of Signal Corps and is rated as a junior military aviator on the date indicated after his name: First Lieutenants Clinton W. Howard, Field Artillery, April 6, 1917; Benjamin G. Weir, Infantry, April 7, 1917; Earl L. Naiden, Cavalry, April 8, 1917; Thomas J. Hanley, Jr., Infantry, April 9, 1917; Benjamin W. Mills, Infantry, April 10, 1917; George Pulsifer, Jr., Infantry, April 11, 1917; Harry B. Anderson, Cavalry, April 12, 1917; Walter W. Wynne, Cavalry, April 13, 1917; James F. Byrom, Infantry, April 14, 1917; Joseph T. McNarney, 21st Infantry, April 15, 1917.

Leave one month, about April 5, 1917, to Capt. Josiah C. Minus, retired, supply officer, Aviation Section, Signal Corps, San Antonio. (March 23, S. D.)

Signal Enlisted Reserve Corps

Sergt. Marcus H. Rice, Aviation Section, S. E. R. C., from duty at Mineola, Long Island, N. Y., to Curtiss Aviation School, Miami, Fla., for duty. (April 4, War D.)

First Lieut. William A. Reed, Infantry, D. O. L., to Fort Sam Houston for examination as to his physical fitness for service in the Aviation Section of the Signal Corps. (April 7, War D.)

Second Lieut. Lawrence C. Ricker, retired, to active duty and to Mineola, Long Island, N. Y., for duty. (April 7, War D.)

First Lieut. Arthur Boettcher, Infantry, D. O. L., from duty at Signal Corps Aviation School, San Diego, to Fort Omaha, Neb., Balloon School, for duty. (April 9, War D.)

To be first lieutenant, Sig. (Avia. Sec.), O. R. C., from March 1, 1917: Woodward, Warren O., 13, Oct. 21, 1889, Chicago, Ill.

Officers' Reserve Corps

Potter, Nathaniel H., 2, Nov. 16, 1878, Rochester, N. Y. To be first lieutenant, Sig. (Avia. Sec.), O. R. C., from March 1, 1917: Low, Seth, New York, N. Y.

To be first lieutenant, Sig. (Avia. Sec.), O. R. C., from March 6, 1917: Meyer, Cord, New York, N. Y.

To be first lieutenant, Sig. (Avia. Sec.), O. R. C., from March 19, 1917: Schauffler, William G., jr., Lakewood, N. J.

Board of Officers Created

A board to consist of Capt. Arthur R. Christie, junior military aviator, S. C.; Capt. Ralph Royce, junior military aviator, S. C., and First Lieut. Polk D. Brown, M. R. C., is appointed to meet at Signal Corps Aviation School, Memphis, Tenn., for the examination of persons for appointment as officers in the Aviation Section, Signal Officers' Reserve Corps. (April 7, War D.)

Group of students and instructors at the Curtiss Aviation School at Miami, Florida

CURTISS MODEL JN4-B TRACTOR

DUE to the fact that this machine has been widely used for training aviators both here and abroad, the JN type is probably the best known of all the Curtiss models.

It is comparatively light and for its useful load carrying capacity, is very compact. The JN has become so generally regarded as an unusually safe machine on account of its rigid construction and its ease of control, that it is extensively used in training, exhibitions, contests and other work of this character when flights are expected regardless of weather conditions.

The JN4-B is, as are all Curtiss aeroplanes, regardless of size or type, the composite issue of correct theory, fully tested materials, proper design, careful workmanship, accurate assembly and rigid, painstaking inspection.

General Dimensions

Wing span, upper plane	43′-7½″
Wing span, lower plane	33′-11¼″
Depth of wing chord	59½″
Gap between wings	62 3/16″
Stagger	12 5/16″
Length of machine overall	27′-3″
Height of machine overall	9′-10½″
Net weight, machine empty	1405 lbs.
Gross weight, machine and load	1890 lbs.
Speed range	75-43 m.p.h.
Climb in 10 minutes	3,000 ft.
Motor, Curtiss model OX	90 h.p.

Planes

Upper plane is in three sections; lower plane, one section each side of fuselage. Area of upper panels, excluding engine-section and ailerons, 161.2 sq. ft. Lower panels, 152.26 sq. ft. Engine-section panel, 10.95 sq. ft.

Weight of upper panels without sockets or wires, 124 lbs. Lower panels without sockets or wires, 108 lbs. Engine-section panel without sockets or wires, 12½ lbs.

Wing curve, Eiffel No. 36. Ribs lightened; wing contour of pine reinforced with birch strips. Wing beams of spruce, I section. Trailing edges of flattened steel tubing.

Incidence angle, 2°; dihedral angle, 1°; stagger 12 5/16″. There is no sweepback.

Ailerons are 11′-8 3/16″ long, 18⅜″ wide. Area, each 17.64 sq. ft. Weight, each, 13½ lbs. In cross section the ailerons conform to the contour of the main panels, from rear beam to trailing edge. They are hinged to the rear beam of the panel by four hinges each, with a gap of ⅝″ between the beam and the aileron.

Four masts are provided for bracing the overhang. Each mast weighs 1 lb.

Total weight of interpanel wires and turnbuckles, 21.25 lbs. Wing post sockets (for upper, 16.5; for lower 12) 28.5 lbs. Interpanel struts, 28.25 lbs.

Wing covering of Irish linen, coated with five applications of dope.

Fuselage

Maximum width of fuselage, 27″. Maximum depth, (fuselage framework) 34¾″. The tops of upper longerons are located 8 inches above the centre line of thrust. Longerons in forward part of fuselage are of ash, 1¼″ by 1½″ section. In the rear part they are of spruce, 1¼″ by 1¼″ section.

In the vicinity of the motor, the fuselage is covered with sheet aluminum. Doors are provided for access to the motor. The hoods, cowls and radiator are enamelled khaki. All metal fittings and parts (except tubing closed at ends), are copper plated and then enamelled black. The fittings throughout are drop forgings.

Unequipped, the fuselage weighs 154 lbs. The front seat weighs 6 lbs; rear seat, 7 lbs. Miscellaneous fittings, linen covering, throttles, bolts, etc., 36 lbs.

Instruments fitted on the instrument board are as follows: Stewart-Warner tachometer; athward level, 0° to 10°; Creagh-Osborne compass; U. S. oil gauge, 0 lbs. to 120 lbs: gasoline gauge fitted to tank; instrument board lights. Total weight of the board equipped with the above, 21½lbs. Switches weigh 5 lbs.

Provision is made for carrying tools weighing 17 lbs. and a fire extinguisher weighing 8 lbs.

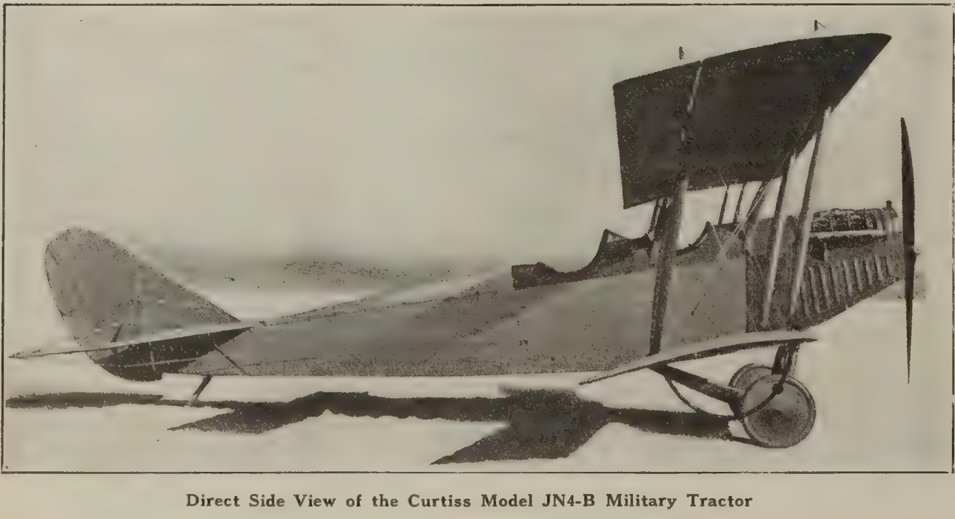
Controls

Dual control is provided in the following combinations: Curtiss-Deperdussin, Deperdussin-Curtiss, double Deperdussin.

The control bridge is of the inverted "U" type, double aluminum tubing. It is equipped with a 16″ aluminum spider, black walnut rim, hand control wheel. The cable guide sheaves are made of aluminum. Weight of the dual control (front, 15.8 lbs.; rear, 16.7 lbs.), 32.5 lbs. Control leads weigh 9 lbs.

The rudder operates 30° to either side of the longitudinal axis. Corresponding movement of the rudder bar is 45° each side of the centerline.

Total movement of the elevators is 60°, i.e., 30° above or below the neutral position. The corresponding movement of the control bridge is about 64°. The efficiency ratio is about 2.3; 1 at the center of the control.



Direct Side View of the Curtiss Model JN4-B Military Tractor

Landing Chassis

The landing gear is the two-wheel "V" type, with streamlined struts. Axles are guided in bronze saddle fittings. Wheels equipped with 26″ by 4″ tires. Span between wheel centers (tread), 63 11/16″. Weight of wheels, each 21 lbs. Struts, axle, wiring and fittings weigh 50 lbs.

Below the outer interplane struts, rattan wing skids are fitted, weighing 2½ lbs. each.

The tail skid with braces weighs 8 lbs.

Tail Group

The stabilizing plane is non-lifting. The top is slightly cambered. Maximum length, 9′-3″; depth, 3′-6″. Surface area, 28.7

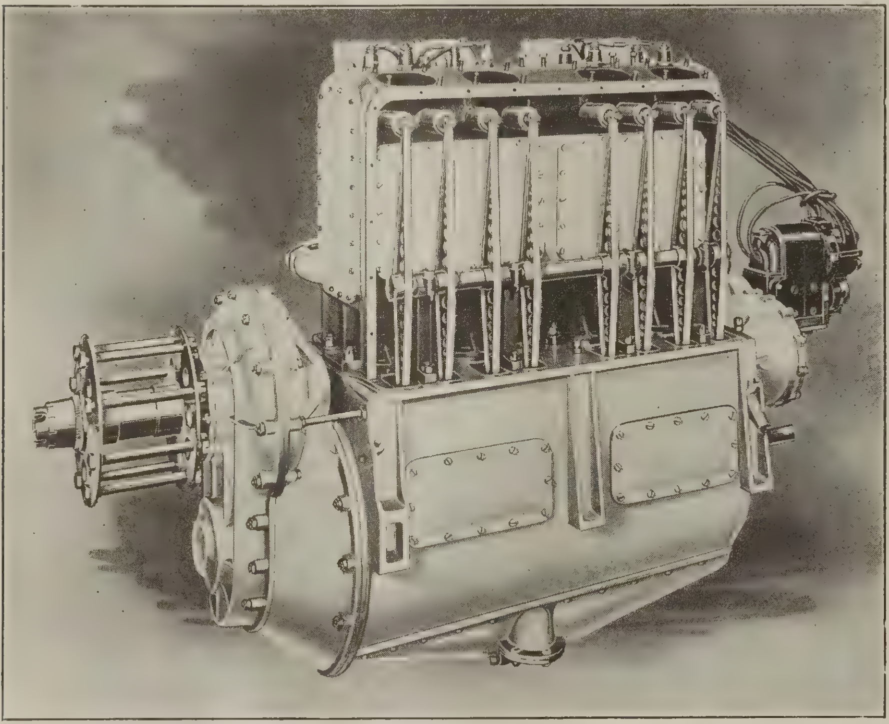
DUESENBERG MOTORS CORPORATION ORGANIZED

One of the most interesting events of the more recent past is the formation of the Duesenberg Motors Corporation of New York City. The new corporation succeeds and takes over the business of the Loew Victor Engine Company of Chicago and the Duesenberg Motors Company of St. Paul. It will build on a commercial scale the efficient motors designed by Fred S. Duesenberg for marine, automobile and aeroplane service. A number of contracts already have been closed with some of the most prominent builders of high class motor boats, automobiles and aeroplanes, and production is already organized on quite a large scale. The official statement, which was communicated to AERIAL AGE, concerning the reorganization, is as follows:



The Duesenberg 16-valve, 4-cylinder Aero Motor

"The marine models of the Duesenberg Motors were brought out nearly two years ago by the Loew Victor Engine Company of Chicago, and have been in successful operation for some time, and the volume of business on these motors has been large for better than a year, and it is now one of the biggest factors in the marine engine industry. These marine engines are made in two sizes, a six cylinder—6¾ x 7¾ inch—and an eight cylinder—6¾ x 7¾ inch, developing from 200 to 400 horsepower. These two engines will be manufactured in the Chicago plant of the Duesenberg Motors Corporation, and this plant will do nothing else but produce these marine motors.

"The automobile and aeroplane engines manufactured by the corporation are now being built at the new plant located at Edgewater, N. J., this plant having been recently taken over, it previously being one of the big munition plants at Edgewater. Consequently its equipment was almost ideal for the manufacture of motors of the Duesenberg type, and it was only necessary to make a very few changes in the machinery and equipment of this plant to make it a highly efficient unit for the purpose desired. Manufacturing is now going on at the Edgewater plant, and production is rapidly climbing to the point where it will be possible to at least fill the immediate orders that the corporation has booked.

"The stockholdership of the Duesenberg Motors Corporation is in the hands of some of the best known men in business and financial circles of the United States. The officers of the new corporation are as follows: President, J. B. Harbeck; assistant to the president, E. P. Decker; secretary and treasurer, H. A. Wing; vice president, Charles Stollberg; general manager in charge of manufacturing, Charles B. Page; general sales manager, N. G. Rost; purchasing agent, G. H. Beilstein; chief engineer, F. S. Duesenberg; assistant engineer, A. S. Duesenberg; assistant engineer and naval architect, Morris M. Whitaker; assistant engineer, specializing in aeronautical division, F. G. Robinson.

"From this list it will be seen that the corporation already has established a highly efficient organization, made up of men thoroughly experienced in the various lines.

"The Board of Directors of the Duesenberg Motors Corporation is as follows: J. R. Harbeck, F. S. Wheeler, Charles Stollberg, Karl Breckenbridge, L. M. Welles, Frank B. Page.

"Mr. J. R. Harbeck has been president and managing director of the Loew-Victor Engine Company for the past three or four years, and it was under his active management that the Duesenberg Motors were developed for marine and aeroplane purposes. Mr. Harbeck will devote even more of his personal time and attention to the affairs of the Duesenberg Motors Corporation than he even did to those of the Loew-Victor Engine Company.

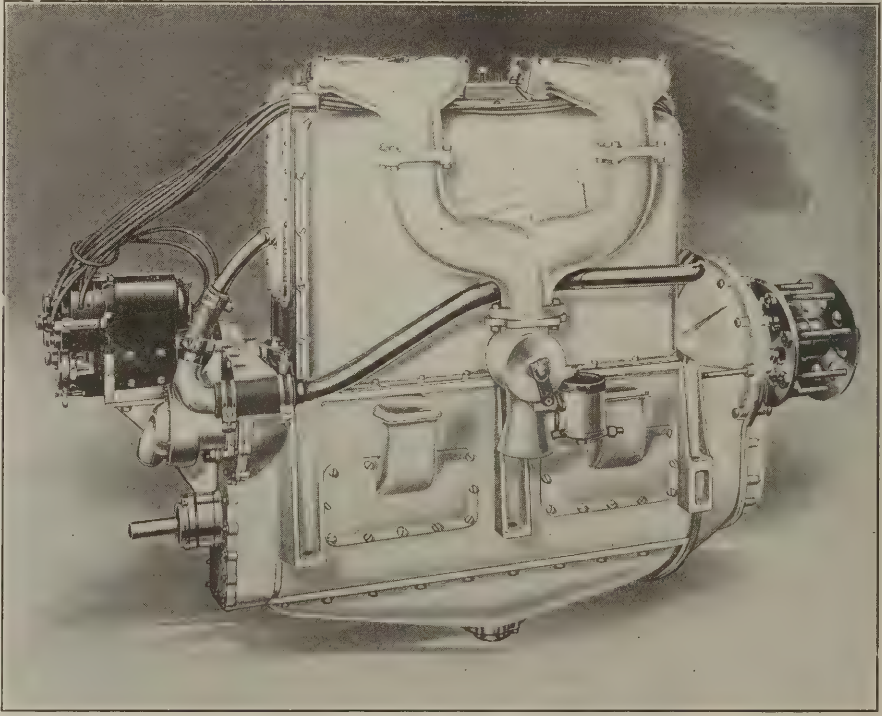
"Each of the three types of motors will be built on the same general design, differing only enough to adapt them to their individual requirements. The Duesenberg design has proven itself in actual service for a number of years. Better than sixty per cent of all racing cars on American speedways in 1916 were equipped with Duesenberg Motors. Duesenberg Motors were installed in the first motor boat to make a mile a minute speed. Duesenberg Motors were installed in the boat that won the displacement runabout classic at the Miami regatta this year. Duesenberg motors are installed in seaplanes now in the service of the United States Navy.

"The Duesenberg four and six cylinder automobile motors simplify the evolution of the Duesenberg design, which has passed through the severe test of automobile and motor boat racing, and now occupies a dominant position in the field of internal combustion engine design.

"The racing game has refined this design to a hitherto unattained degree. It has made it possible to build an engine developing more power in proportion to bore and stroke than any other motor in America. The weight, however, has been kept well within the necessary limit, and the motors are wonderfully compact.

"The Duesenberg design, as applied to automobile and aeroplane motors, has been worked out in full detail, and put on a commercial and manufacturing basis, and the plant at Edgewater, N. J. is now producing these engines and is now in a position to accept and efficiently handle large orders."

We hope to publish in our next issue a complete description of the new Duesenberg 4 cylinder motor.



The Duesenberg 16-valve, 4-cylinder Aero Motor

MUFFLERS FOR AERONAUTIC ENGINES

By PROF. H. DIEDRICHS and PROF. G. B. UPTON, of Cornell University[*]

I. THE PROBLEM.

The necessity for muffling the exhaust of aeroplane engines is hardly open to argument. The objects in view are the minimizing of noise to delay detection in military service, to protect the general public, particularly those living near aviation fields, and lastly to give the operator a better chance to know what the rest of his power plant is doing. The last point is perhaps even now of little importance, as an exhaust pipe long enough to end behind the operator is quite enough to make the exhaust noise less prominent than some other rackets.

A study of the general problem of silencing the areoplane power plant, not only in the laboratory but also by means of observing aeroplanes in a large number of flights, has led to certain conclusions, none of which are, however, new. In the first place the exhaust noise is not the only disturbance to be dealt with, although perhaps the most important, because the staccato barks of open exhaust carry to greater distances than the other attendant noises. It is, however, not a matter of great difficulty to so far suppress these barks that the exhaust noise ceases to be the most prominent in relation to some others. As a matter of fact, a simple pipe of sufficient length will do this for the high-speed multicylinder engines, and we understand that some American and German planes are using this scheme. It serves at least to protect the operator, even if it does not go a great way toward actually suppressing the pulsations as far as an observer at a distance is concerned. The very fact that the impulses follow so rapidly upon one another seems to make the problem of taking off the "bark" easier, for we found it much harder to muffle single-cylinder slow-speed engines.

Assuming, however, that a successful device for completely muffling the exhaust can be found, we should still have to deal with other noises, such as the hum of the propeller, the singing of gears, and the rattle of the valve gear. It will be admitted that all of these sources of noise can be minimized, but elimination does not seem to be in the realm of possibility.

On the 8-cylinder engine used for our last experiments the propeller of the fan brake caused a deep, more or less musical note, which appeared to come from the crank case. This noise disappeared when the blades were removed from the fan arm, and the engine was operated at speed under its own power, swinging only the arm. The same sort of humming note can be identified in connection with planes in flight at considerable altitudes and distances. To silence this disturbance presents a problem on which at present the writers have no suggestions, except that slower speed (geared) propellers might help.

Another source of noise is in the valve gear. In the case of the engine under test this consisted in a sort of rattling hiss at high speeds. It can be easily identified when the observer is close by. In planes of flight at some distance from the observers the noise would appear to be drowned in the exhaust roar and in the hum of the propeller. In any case this disturbance can be minimized by accurate adjustment. But it is difficult to see how the valve slap can be entirely eliminated.

The last source of noise is in the gears. This can be partly suppressed at least by the use of spiral gearing and by accurate machine work and mounting.

These four sources of noise are the principal ones requiring attention. We would place them in order of importance: (*a*) Exhaust noise, (*b*) propeller noise (*c*) valve-gear noise, (*d*) gear noise. We believe that it is most important to suppress the exhaust noise, because its staccato barks will undoubtedly advertise the rising of a plane sooner than the other three by reason of its greater carrying power. But the problem of the other noises remains; and we are further of the opinion, based on our experience in the past year, that the exhaust noise can be so far suppressed with comparatively simple means that it forms the smallest source of the disturbance of the four. We will not venture to predict complete suppression. Any muffler construction in connection with its manifold will have to take in some one of its parts the full force of the original blow, and since lightness of construction is one of the requirements calling for thin walls the chances are that there will always be more or less of a pulsating roar, at least near the engine. We have so far not reached the stage of considering this part of the problem.

Confining our attention now to the particular problem in hand, the silencing of the exhaust, a successful device will have to meet three requirements: (*a*) Satisfactory suppression of noise with least back pressure, (*b*) lightest possible weight, (*c*) greatest durability. For the last year we have confined our attention to the first of these, believing that the other two could be successfully met if the first requirement were satisfied.

II. PRESENT DEVELOPMENT OF MUFFLING DEVICES.

The state of perfection at present reached in the muffling of auto-engines is well known. As far as this problem is concerned, it may be considered solved as regards suppression of noise. Not a great deal of scientific data are available. Some tests were carried on at the University of Michigan, an abstract of the report being published in the *Horseless Age* for May, 1915. Five types of mufflers were tested and investigated as to back pressure, horsepower loss, and muffling ability. Of the five, the one given the highest rank on all three counts has the construction shown in figure 1. The engine used was a nominal 25 horsepower automobile engine (Hudson 6-54, 4⅛ by 5¼ inches), the test speed ranging from 750 to 1,300 revolutions per minute. At the latter speed the brake horsepower reached 40. The muffler weighed 14.5 pounds, which is equivalent to 0.36 pound per horsepower, based on the maximum power, and had a volume capacity of 847 cubic inches, which is approximately nine times the cylinder displacement. All of the other mufflers weighed more, so that 0.36 pound per horsepower may perhaps be considered the present minimum in automobile practice. This is a feature, however, of not as great importance as it would be in aeroplane practice. This muffler showed a back pressure of only slightly over 1 pound at the maximum speed, the loss of horsepower being only 1.4 per cent. at the maximum. For automobile practice this must be considered an excellent showing.

We were fortunate enough to obtain the loan of two mufflers especially designed for an 8-cylinder V-type engine and commercially manufactured. The smaller one of these mufflers is intended for a single cylinder and is 5 inches in diameter by 12 inches long. It has the construction shown in figure 2. The larger one, intended for four cylinders, is 5 inches in diameter and 28 inches long. The internal construction is probably made up of a multiplication of the elements of the smaller muffler. Both of these mufflers were tested by connecting them directly to the ends of the side manifolds by means of slip joints. Speed changes were noted by forcing the mufflers on and pulling them off by hand. This method of testing puts a heavier load on the smaller muffler than it is designed for, but since we did not have eight of them this was the only method available.

The tests on the smaller mufflers resulted as follows:

Throttle position on scale.	Back pressure, "Hg mufflers.		Corrected revolutions per minute, mufflers.		Back pressure increase, "Hg.	Speed drop.	
	Off.	On.	On.	Off.		Revolutions per minute.	Per cent.
4	0	0.25	933	933	0.25	0	0
5	0	.55	1,071	1,071	.55	0	0
8	0	1.90	1,257	1,143	1.90	7	0.52

Throttle position on scale.	Brake horsepower, mufflers.		Per cent. horsepower loss.	Brake mean effective pressure (pounds per square inch), mufflers.		Loss of brake mean effective pressure, pounds.
	Off.	On.		Off.	On.	
4	28.8	28.8	0	48.6	48.6	0
5	43.4	43.4	0	64.0	64.0	0
8	69.8	68.6	1.5	87.7	86.8	0.9

The larger muffler gave the following results:

Throttle position on scale.	Back pressure, "Hg mufflers.		Corrected revolutions per minute, mufflers.		Back pressure increase, "Hg.	Speed drop.	
	Off.	On.	On.	Off.		Revolutions per minute.	Per cent.
4	0.01	0.64	928	928	0.63	0	0
5	.025	1.5	1,066	1,060	1.48	6	0.51
8	0	4.0	1,268	1,240	4.0	28	2.24

Throttle position on scale.	Brake horsepower, mufflers.		Per cent. horsepower loss.	Brake mean effective pressure (pounds per square inch), mufflers.		Loss of brake mean effective pressure, pounds.
	Off.	On.		Off.	On.	
4	28.3	28.3	0	48.1	48.1	0
5	42.8	42.1	1.5	63.4	62.7	0.7
8	72.1	67.4	6.6	89.7	85.8	3.9

It will be noted from these figures that, in spite of the unexpected load, the smaller muffler gives the better results. As a matter of fact, the horsepower loss at rated output for the larger muffler is prohibitive. On the other hand, several observers judged that the larger muffler more effectively quieted the exhaust noise. The two, however, are so close together regarding this point that it became difficult to judge of the difference in connection with the other noises. Our conclusion is that both mufflers are good with respect to quieting and that the greater efficiency of quieting in the larger muffler is bought at too great an increase in the back pressure. We have no

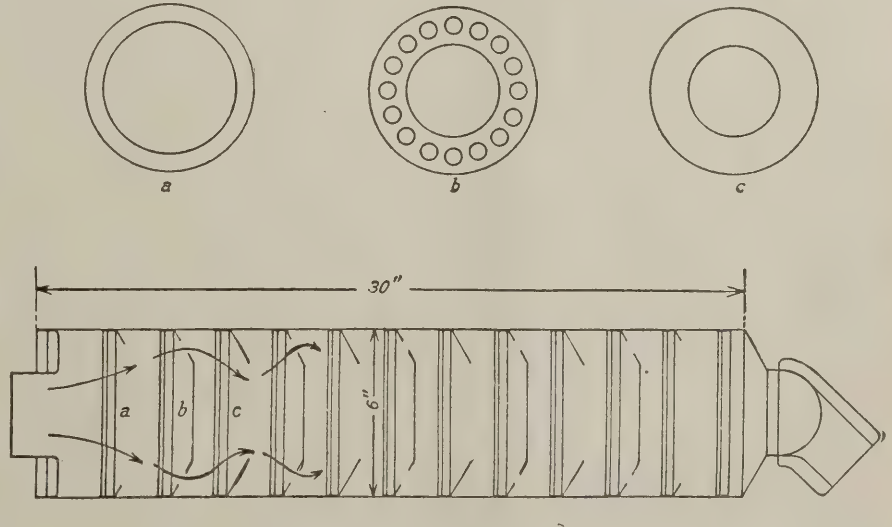


FIG. 1.

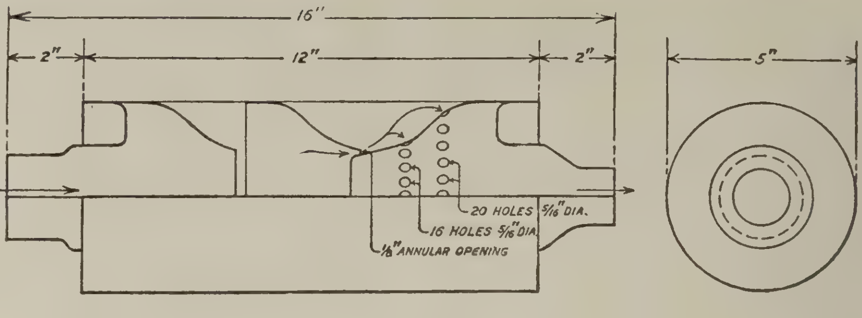

FIG. 2.

hesitation in saying that the smaller muffler is as good a solution of the problem as we have yet seen.

III. THE EXPERIMENTS.

Experiments with devices constructed by us were carried out partly on a single-cylinder slow-speed machine, partly on a 60-horsepower 4-cylinder Maxim engine, and lastly on an 8-cylinder Curtiss engine.

The principle underlying the action of muffling is simple. At the moment of opening of the exhaust valve the pressure conditions are such that the gases issue at velocities of approximately 2,000 feet per second. The problem is to reduce this velocity below that of sound (1,100 feet per second) without causing undue back pressure. The bark of the open exhaust is due to the issuing of the gases at velocities higher than that of sound, and the main disturbance is suppressed as soon as the velocities are brought below 1,100 feet per second. The means at hand to accomplish this are: (*a*) Cooling of the gases to reduce volume, (*b*) gradual expansion, (*c*) internal friction and eddy currents in the gas, and (*d*) frictional resistance between gases and containers and baffles. Of these the first mentioned is practically negligible, as the degree of cooling can not be great in the time available.

To bring into play the other three means would require a construction having the following essentials: (*a*) An entrance chamber several times the cylinder volume, to allow the unrestricted transfer of the gases from the cylinder to this chamber, for the purpose of preventing undue back pressure, and (*b*) one or more expansion chambers so provided with baffles as to break up the gas currents in such a manner as to cause decreasing velocity by means of both expansion and friction.

As far as application to the engine is concerned, three solutions are possible. The first is to use individual mufflers for each cylinder. This scheme at first sight has a good deal in its favor, but upon analysis several prohibitive disadvantages will appear. In the first place, there is no doubt that, say, 8 small mufflers will weigh more than 2, each taking care of 4 cylinders. In the case of the commercial muffler above mentioned, the weight relation is 15 pounds for 4 individual mufflers to 6 pounds for the single muffler doing about the same work. Further, the advantage that a 4-cylinder manifold will in itself act partly as a muffler is lost, and we would have the individual bark of each cylinder to deal with. And, finally, where the scheme had been tried it was found very difficult to properly stay so many mufflers as to prevent dangerous vibrations.

The second scheme is to combine manifold and muffler, i. e., to internally construct the manifold to convert it into a complete muffler. This scheme also looks good at first sight; but in order to provide sufficient volume a manifold so constructed would be of large diameter, since the lateral distance between cylinders is restricted, and it is a question whether it is desirable to place so large a heat-radiating surface next to the cylinders and the structural members of the plane. The question of adding weight at that height from the base to the side of the cylinders is also of importance with relation to possible excessive vibration. We tried one scheme of this kind on the Maxim engine, as below noted, but with doubtful success.

The third scheme is to use a regular manifold and to connect this by means of flexible hose to the muffler proper. This allows of any convenient placing of the muffler with reference to engine and to operator. The length of exhaust hose is of no importance, consistent only with low back pressure, and, given this, a considerable length of hose or pipe is a positive help to the muffler. We believe on all counts that this combination is the best solution.

The first experimental construction embodied the idea of making the entrance space a centrifugal whirl chamber in which the gases were to lose part of their kinetic energy by mutual interference before passing out through holes or slots in a central pipe. It was made up out of a 4-inch tee, the side branch of which was capped, and the cap then bored and threaded for the 1½-inch exhaust pipe, of a 6-horsepower oil engine. The opening from this pipe was placed eccentrically in the cap, so that the gases entered the 4-inch tee tangentially. One of the straight-run openings of the tee was plugged, while the other was bushed to receive a 1½-inch pipe. The pipe could be extended varying distances into the tee by a long thread. Tests were made with this central pipe not perforated in any way, but open at the end. The best results were found when this pipe extended to within ½ inch of the opposite plug. Later the end of the central pipe was plugged and the pipe perforated with holes, a second one was then tried perforated with slots. In these cases the gas, after whirling around in the chamber, found its way into the central pipe through the holes or slots and so on out. All of these devices were only moderately successful and did not seem to promise much.

It was then thought desirable to improve the entrance conditions to the whirl chamber by gradually broadening the entrance pipe, thus introducing the gas tangentially in a wide band. Figure 3 shows the construction. Three concentric central pipes, a 4-inch, a 3-inch, and a 2-inch were used. the latter being open to the air at both ends. The central pipes were slotted, the 4-inch and 3-inch pipes as in figure 3-a, the 2-inch pipe as in figure 3-b. It was found that the direction of the slots in the inner pipe caused the gas to move out of one end of the pipe, creating a distinct suction on the other end. This device showed up much better than the crude first construction. It was estimated to cut out 80 per cent. of the noise. Back-pressure readings were not taken, as we were as yet mainly interested in noise reduction.

The success of this device on the particularly vicious bark of the oil engine on which it was used led us next to construct a combined manifold and muffler of this type for the Maxim engine. The main features of this muffler were: An expanding, flattened nozzle from each cylinder to lead the gas tangentially into the shell, a common annular chamber between the largest inserted pipe and the shell into which the exhaust from all cylinders first entered, a series of four pipes 2, 3, 4, and 5 inch, with perforations so arranged that the gas must first pass through the wall of the 5-inch pipe in a slanting direction, and having attained a certain velocity in this direction must turn and pass through the 4-inch in the opposite direction because of the slotted openings. Another turn was necessary to pass through the 3-inch, and finally through the 2-inch to the atmosphere.

We did not succeed in getting a very good idea of the action of this manifold muffler, as the Maxim engine, which had been loaned us, was recalled. The trial run made promised fairly well, but the end joints between the pipe were not tight and considerable gas escaped. As built, with a cast-iron jacket, this muffler proved exceedingly heavy.

We have not done anything more with the manifold mufflers, but intend to try out one or two other ideas, which, however, have so far reached only the design stage.

The last work was done on an entirely different type from that above described. The underlying idea in this type is to provide an ample receiving chamber, and then as the gases work toward the outlet, to provide gradually increasing resistance, until the pulsations are toned down and the gas issues in streams of fairly constant velocity at speeds below that of sound. This should substitute for the bark a hiss like that of escaping steam of low pressure. It might be pointed out that the well-known Maxim muffler is of this general type. Only in this muffler the circular receiving chamber is followed by an annular space surrounding the former, which space is packed with baffle plates of spiral form. The gases here lose velocity by internal friction and surface friction. No attempt is made to utilize the idea of a gradually increasing resistance to the flow toward the outlet.

The scheme was tried out on the 8-cylinder Curtiss engine. Two manifolds of light-weight steel were cross connected by another manifold, so that we finally had a single discharge and only one experimental muffler had to be built. The construction of this is shown in figure 4.

We adopted for this muffler the prismatic form for two reasons. In the first place, it is easier to construct than the circular form; and secondly, we believe that this form may have some advantages over the circular form for stowing away on an aeroplane. The essential features are as follows: Gradually expanding entrance nozzle A, a receiving chamber B, two expanding and retarding chambers C and D. About half of the two expansion chambers are filled with closely packed wire gauze of decreasing mesh, in the following order going toward the outlets:

	Layers.
3½ inches of 2 meshes per inch	28
2½ inches of 3 meshes per inch	26
2 inches of 4 meshes per inch	24
1½ inches of 5 meshes per inch	18
1½ inches of 8 meshes per inch	20
1 inch of 12 meshes per inch	25

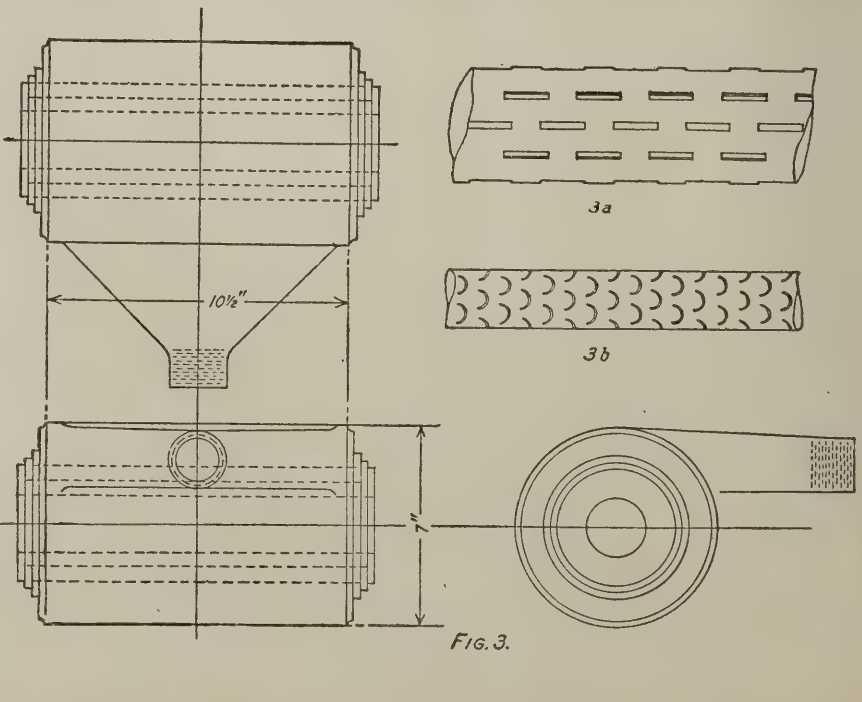
This muffler was connected to the outlet of the cross manifold by a short piece of flexible metallic hose and in parallel with a quick-closing gate valve. By this means the exhaust could be instantly changed from muffler to open air and back again. An electric tachometer, carefully calibrated, was used to note changes in speed, and the back pressures were observed by means of mercury manometers connected to the side manifolds near their connection to the cross manifold.

Trials with this muffler showed the following:

(*a*) The application of the side manifold and of the cross manifold alone served to tone down the barks considerably. The back pressure observed with only the side manifolds was negligible and with the cross manifold showed about 0.3-inch Hg. at rated output of 70 horsepower.

(*b*) The application of the muffler raised the back pressure only about 0.1-inch Hg., which is a very good result. The power loss is negligible.

(*c*) As far as muffling is concerned, three



3a

3b

FIG. 3.

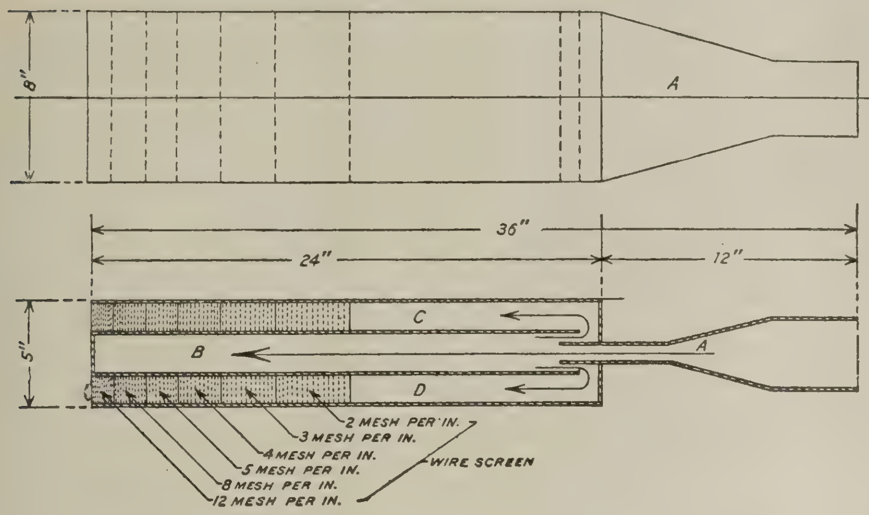


FIG. 4.

observers judged that the exhaust noise was cut out to the extent of about 50 per cent.

We believe that the muffling efficiency of this construction can be improved, and we have already started to work out an improved design. The virtual absence of back pressure is the most encouraging feature. Objection has been made to this design on the score of carbon clogging of the wire gauze. Only a service run of some hours' duration can prove this point.

At present we have not used any quantitative scheme of judging degree of noises, but have depended upon several independent observers. This scheme is not wholly successful on account mainly of the other noises present besides the exhaust. As a matter of fact, to get any idea at all of this matter in connection with the Curtiss engine, it became necessary to extend the pipe through a window and to place the muffler outside of the building. In the University of Michigan tests, above quoted, besides using independent observers, a telephone was used, the observer in a room some distance away noting the distance between himself and the telephone at which he failed to distinguish the exhaust noise. The receiver was placed near the engine. What such a scheme would show in our case is problematical, but we intend to try it out the coming year. We wish gratefully to acknowledge in this connection the active help of Profs. V. R. Gage and C. A. Peirce, of the Sibley College faculty, and the assistance and facilities supplied by the Thomas Aeromotor Company, of Ithaca, N. Y., and the Curtiss Aeroplane & Motor Corporation, of Buffalo, N. Y.

Further experiments will be made on this type of muffler construction and the determination of the laws affecting feed back pressure power loss are already being investigated and will be the subject of a future report.

(*Continued from page* 193)

lifted off their cams by the small lifting cam B, the lip of which engages with the small triangular projecting on the head of the tappets when the hand lever A is depressed. The details of this lifting mechanism are clearly shown in fig. 18. All the valves, both the inlet and exhaust, are thus opened in the cylinder head, and at the same time the lever A, by a connection of levers, closes the exhaust passage to the silencer by partially rotating the water-cooled barrel valve or exhaust throttle D in the exhaust manifold.

The exhaust ports and the outlet in the exhaust manifold are consequently in communication with a secondary outlet pipe that leads to a large suction hand pump E, by which gas is sucked into the cylinders from the two carbureters through all the inlet valves, as indicated in fig. 17, showing the engine with all the valves open. When the cylinders are charged, the valves are returned to their normal positions by the lever A, and the valve D automatically opens the exhaust outlet to the silencer in the normal running position and closes the pipe leading to the suction pump E. Ignition is then effected by means of a geared-up Bosch hand-starter magneto.

Normal ignition is by two Bosch magnetos—type 2H6—supported on a duplex bracket extension of the crank case in front of the engine, the magneto being driven by spur gearing off the crank-shaft bevel gear that also drives the water accelerator.

Two Bosch sparking plugs per cylinder are fitted, one on each side of the cylinder, the plugs being screwed into the combustion chamber directly below the valves, as can be seen by reference to sketches 17 and 18.

The following are a few figures in connection with the engine:

Stroke bore ratio, 1.266:1.

Stroke volume of 1 cylinder, 3357.58 cu. cm., 204.8 cu. in.

Total stroke volume of engine, 20145.48 cu. cm., 1228.8 cu. in.

Area of 1 piston, 176.715 sq. cm., 27.40 sq. in.

Total piston area of engine, 1060.29 sq. cm., 164.40 sq. in.

Clearance volume of 1 cylinder, 680.00 cu. cm., 41.48 cu. in.

Piston speed, 1495 ft. per minute.

Brake mean effective pressure, 107.4 lb. per sq. in.

Cu. in. of stroke vol. per b.h.p., 6.15 cu. in.

Sq. in. of piston area per b.h.p., 0.822 sq. in.

H. P. per cu. ft. of stroke vol., 282 b.h.p.

H. P. per sq. ft. of piston area, 175.4 b.h.p.

Area of inlet valve ports (each), 18.09 sq. cm., 2.80 sq. in.

Total inlet valve port area per cylinder, 36.18 sq. cm., 5.60 sq. in.

Max. lift of inlet valves (h), 9.3 mm., 0.366 in.

Area through each inlet valve ($\eta\ d\ h$), 14.024 sq. cm., 2.175 sq. in.

Total area through inlet valves per cylinder, 28.048 sq. cm., 4.350 sq. in.

Gas velocity through inlet valve ports, 122 ft. per sec.

Gas velocity through inlet valves, 157 ft. per sec.

Ratio of piston area/area through inlet valves, 6.3:1.

Area of exhaust valve ports (each), 9.621 sq. cm., 1.49 sq. in.

Total exhaust port area per cylinder, 28.86 sq. cm., 4.47 sq. in.

Max. lift of exhaust valves (h), 7.88 mm., 0.310 in.

Area through each exhaust valve ($\eta\ d\ h$), 8.66 sq. cm., 1.342 sq. in.

Total area through exhaust valves per cylinder, 25.98 sq. cm., 4.026 sq. in.

Gas velocity through exhaust valve ports, 153 ft. per sec.

Gas velocity through exhaust valves, 170 ft. per sec.

Dimensions of crank webs, 96×23 mm., 3.78×0.98 in.

Bearing, flywheel end, 90×66 mm., 3.54×2.60 in.

Protected area, 59.4 sq. cm., 9.2 sq. in.

Other bearings (6), 64×66 mm., 2.52×2.60 in.

Projected area (each) 42.24 sq. cm., 6.54 sq. in.

Total projected area of crankshaft bearings, 312.84 sq. cm., 48.45 sq. in.

Crank pin bearings (each), 72×66 mm., 2.83×2.60 in.

Projected area, 47.50 sq. cm., 7.36 sq. in.

Gudgeon pin bearing, 110×38 mm., 4.33×1.49 in.

Projected area, 41.80 sq. cm., 6.48 sq. in.

Length of connecting rod between centres, 312 mm., 12.282 in.

Ratio of connecting rod to crank throw $\frac{1}{r}$ 3.29:1

No. and diameter of big end bolts, four 14 mm., 0.551 in.

Diameter of camshaft, 21 mm., 0.826 in (diam. over splines).

No. of camshaft bearings, 5.

WEIGHTS OF VARIOUS PARTS.

Crankshaft, complete with camshaft drive pinion, bevel gear for driving water pump, and worm for driving cross-shaft for oil pump, 45.00 kilos, 99.208 lbs.

Steel flywheel, 30.40 kilos, 67.02 lb.

Piston, complete with gudgeon pin and rings, 4.92 kilos, 10.84 lb.

Gudgeon pin, 0.67 kilos, 1.476 lb.

Connecting rod complete, 4.895 kilos, 10.78 lb.

Weight of reciprocating part of connecting rod, 1.75 kilos, 3.86 lb.

Total weight of reciprocating parts per cylinder, 6.67 kilos, 14.70 lb.

The following test results of the material employed in the engine are of certain interest.

The crankshaft steel gives Brinell numbers as follows:

Front web, No. 285=65 tons steel.

Rear web, No. 321=72 tons steel.

Tensile and impact pieces prepared from the cylinder holding-down bolt give the following:

Yield point, 52.85 tons per sq. in.

Maximum stress, 58.65 tons per sq. in.

Elongation on 1.41 in., 19.15 per cent.

Reduction of area, 52.6 per cent.

Brinell hardness, No. 271.

Impact, 20.5 ft. lb.

A test from a portion of the aluminium crank case gives the following:

Maximum stress, 9.1 tons per sq. in.

Elongation on 2 in., 1.5 per cent.

Elongation on 4 in., 1.25 per cent.

Reduction of area, 3.24 per cent.

Bend through, 11 deg. broken.

The folowing results were obtained on analysis:

ALUMINUM.

Zinc, 12.34 per cent.

Copper, 1.06 per cent.

Iron, 0.86 per cent.

Silicon, 0.47 per cent.

Aluminium, 85.27 per cent.

Inlet valve spring contains no vanadium.

Exhaust valve: Vanadium present (percentage small).

THE 200 H. P. MAYBACH ENGINE

(Continued from page 113)

The method of obtaining a constant feed to the jet without the usual float chamber is as follows: Petrol is fed into the upper reservoir seen on the right-hand side at the top of fig. 7. From this reservoir it flows *via* the gauge filter-ended feed pipe downwards to the jet container, which, it will be noticed, is divided into two compartments by an inclined wall having a passage at its base leading into a short, wide "sealing" chamber or tube that is open at the top. At the top of the inclined wall is an air vent leading into the second compartment, and to the left in the top wall of the latter is another vent leading to the outer atmosphere. (It should be noted that this air vent does not in the actual construction come near the air intake port in the side of the throttle, and is only shown in that position owing to the exigencies of diagram making.) The hole forming the jet proper is drilled through the top face of a short cylindrical boss projecting up from the cover of the jet container. The exterior of this boss forms the bearing upon which the eccentric jet cap rotates. Downwards from the cover, and surrounding the jet boss, there depends a tube open at the lower end and reaching almost to the bottom of the "sealing" tube referred to above. Gasoline, then under the influence of gravity, flows from the upper reservoir into the first compartment and thence into the "sealing" tube, from which the jet draws as much as required; any surplus flow rises over the edge of the "sealing tube" and runs away into the overflow pipe at the base of the second chamber seen to the left in the diagram. As the upper reservoir tank and the "sealing" tube are both open to atmospheric pressure, the feed of petrol to the jet is unaffected by variation in altitude; that is to say, the gasoline level in the jet remains constant during any change in atmospheric pressure, as is not the case with the ordinary float feed. If more gasoline than required is fed into the upper reservoir it is carried away by the overflow pipe therein down into the second chamber, and thence, together with the surplus from the "sealing tube," away to the fuel supply regulator, or float chamber, shown in fig. 9.

In the fuel feeding system to the carbureters there are three units—a pressure pump, a valve box, and a float chamber or fuel regulator. The relative connection of these can be seen in the arrangement diagram (fig. 1).

Figs. 5 and 10 show the fuel pump system. An extension of the shaft driving the governor carries a small crank pin from which two connecting rods proceed to two pistons and pump cylinders set at right angles.

The horizontal or fuel pump has three connections, viz., a small bore pipe connected to an auxiliary hand pressure pump, and a pipe to dial gauges carried on the side of the crank case, while the other connection proceeds to the cylindrical fitting containing the valves for the pump. This fitting is bolted to the bottom of the crank case, as indicated at A in the general layout diagram (fig. 2), and is shown in detail in fig. 11.

The fitting illustrated in figs. 11, 12, and 13 is in appearance a cylindrical vessel, and is bolted at its top to the rear end of the bottom half of the engine crank case, as shown at A in fig. 2. It is divided into two portions, absolutely separate, the top one being devoted to the oil filtration, and the lower one to the petrol system.

- C Inlet valve
- D Main bearing cap.
- E Oil catcher (aluminium casting).
- F Crankshaft

Worm (4 Thds) driving transverse Shaft for Oil Pumps & lubrication Governor. Ratio 8/1

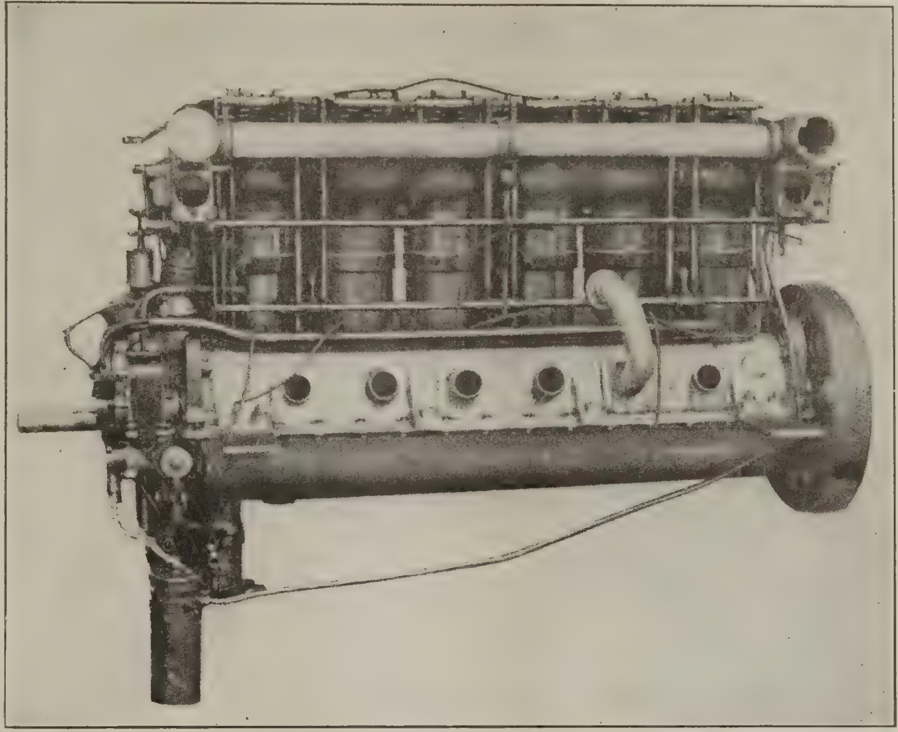
Bevel Wheel 34 Teeth approx. 8 M/M pitch driving Water Pump. Ratio 34/17.

The two portions presumably are located together merely for convenience—it may possibly be with the obeject of warming the petrol, and at the same time to assist in cooling the oil. Into the side of the top half a pipe leads from the oil pump, and the oil, passing through the gauze filter, issues from the pipe that leads to the main bearings (fig. 3).

The bottom portion of the device forms an air vessel and valve box for the pump used in the petrol supply system, and will be seen from fig. 1 to be connected with the horizontal piston pump shown in fig. 10. On its suction stroke the piston will cause the suction valve to open with a reduction of pressure in the chamber K (fig. 1). Whatever may have been drawn by the pump through K will be forced, on the compression stroke of the piston, through into the larger chamber, from which there is a pipe leading to the reservoirs above the jets of the two carbureters. The pump, therefore, effects delivery of petrol, and the two chambers in connection with the valves are intended to equalize the flow of petrol inwards and outwards in a manner similar to the dome or "air vessel" used on many types of pumps, and commonly seen on the fire engine. As the pump in this case is situated at a little higher level than the air vessel, it is evident that no petrol actually reaches the piston, and that the petrol is effectually pumped without connection with the pumping medium, the difficulty—or practical impossibility—of pumping liquid petrol being fairly well known.

In fig. 9 is presented a diagram, and in fig. 14 a perspective sketch of the mechanism that is in effect the float chamber. This device was carried beneath the base chamber, and well away from the carbureters. It consists of a cylindrical metal tank divided into two compartments, the lower being the larger. In the centre of the bottom of the upper tank ther is a tube depending well down into the lower one. This tube forms the only means of communication between the upper and lower chambers, and its lower portion makes a rough guide for a large float contained in the lower chamber. At its upper end there are two seatings for a double end needle valve. Normally this needle valve is held down on its lower seating by a coil spring. Provision is made that, as the lower tank is filled, the float rises, and a striker plate carried at its base, through the medium of a rod, lifts the needle valve up from its lower seat and causes the top point of it to close upon the seat. The striker rod that effects this is carried centrally on guides in the depending tube, and is divided in the middle, the valves being held apart by a coil spring presumably to give a cushioning as well as a "time" action to the mechanism, allowing the float a certain amount of travel before definite action takes place. The upper seating of the valve communicates with the upper tank, and is enclosed in a cylindrical gauze filter box. To the small chamber containing the needle valves, a pipe from the air vessel is connected, and, since suction from the pump takes effect upon the needle valve chamber, petrol will be caused to flow in from the pipe in the upper chamber of the fuel regulator. This petrol will flow through the lower portion of the chamber shown in fig. 11, and up to the fuel reservoir in the carbureter, any surplus from the carbureter returning down the overflow pipe into the lower half, or float chamber. As soon as this float chamber fills, the float rises, and eventually lifts the double end needle valve off its lower seating until it closes instead on to the upper seating. The suction is thus transferred from the upper chamber to the lower one until the petrol contained therein is used up and the float falls, allowing the needle valve to resume its normal position and the petrol supply its normal flow. There remain two more inlets to the float chamber, one of these being connected to the second carburetter, and the other to a pipe carried sufficiently high to prevent leakage but open at the end to provide an air vent to the float chamber. The fuel regulator device is made necessary by the system adopted for jet feed in the carbureter, a system probably aranged in view of the particular importance of avoiding fire dangers on an airship. The carbureter proper thus contains a minimum of petrol, the bulk supply in the float chamber being well removed from the danger zone of the engine by location beneath the base chamber. The arrangement employed also uses up any surplus petrol that overflows through the jet feed.

In figs 1, 15 and 16 are shown the essentials of a system intended to prevent the engine running if the pressure of oil in the lubricating system fails. Inside the crank case is a short cylinder open at the bottom end and containing a short piston, the rod of which passes through a guide in the cylinder cover and terminates in a collet between which and the cover there is a compressed coil spring. This spring endeavors always to draw the piston upwards into the cylinder on to a stop on the piston rod, the travel on the piston being limited to about three-eighths of an inch. Above the piston a port is provided in the cylinder wall; this leads to a port A, in a circular casing, the centre of which forms the cylinder barrel of a triple piston slide valve, shown in section in the lower diagram of fig. 15. In the one position of the piston valve, the port A is in direct communication through the circular distributor body with the second port G, and G is connected by a pipe to the outlet in the top half of the device shown in fig. 11; that is to say, in brief, that any pressure in the oiling system is communicated to the cylinder and tries to force the piston downwards. Bolted horizontally into the crank case beneath this cylinder is a case containing a spring-loaded plunger, the normal position of which is with the rod projecting into the sump as far as it will go. This plunger case is so placed in the crank case that the rod just clears the piston when the latter is in its highest position. At the outer end of the plunger is a striking arm that engages the end of a small laminated spring fastened to a rocker shaft conected by a series of bell crank levers and rods with the quick thread rising jet damping device shown beneath the jet hole in the diagram of the carbureter. With the plunger in its normal position—that is, projecting inwards to the crank case well under the piston in the manner shown—the dampers are lifted and the jet holes closed, or nearly so, according to the adjustment. An arangement is provided on one side of the engine bearers whereby the plunger rod can be drawn outwards by hand, so that the jets are opened.



The 200 h.p. Maybach Engine

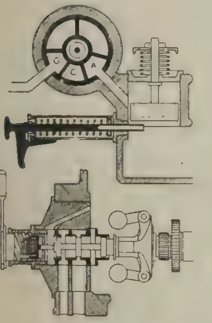


Fig. 15.

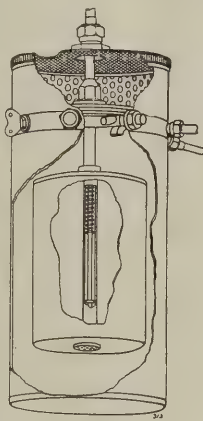

Fig. 14.

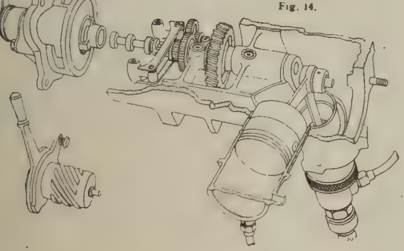

Fig. 16

The operation is probably as follows: Before the engine can be started up the plunger rod must be drawn by hand outwards in order to open the jet dampers. When the engine is started, so soon as pressure exists in the lubrication system, the piston will be forced downwards opposite the interior end of the plunger rod, so that if the grasp on the latter be released it will move inwards only a short distance, because the interior end of the plunger rod will strike against the side of the piston. So long, therefore, that pressure in the lubrication system is maintained, the dampers will be held off the jets, but if pressure fails, the piston will rise under the influence of its spring, and disengage the end of the plunger rod so that the latter will fly inwards, and in so doing cause the jet dampers to cut off the petrol supply in the mixing chambers.

With regard to the triple piston valve contained in the circular distributor body, a section of which is given at the bottom of fig. 15, this consists of a rod with three narrow pistons mounted on it enclosed in a tube, in the circumference of which two groves are cut, each groove being in communication with a port. The rod ends in a fork which engages with a small centrifugal governor driven by gearing from the crankshaft (see fig. 16). The governor rotates the rod and can slide it to and fro against the action of a spring-loaded plunger, shown in the left of fig. 15, which is carried in a case having a quick pitch thead on its circumference, and can be regulated by the lever as to its strength. The normal position of the piston valve rod is such that ports G and A communicate. As the speed of the governor increases, the tendency is to force the rod to the left, thus cutting off port A from port G, and putting port A in communication with the interior of the crank case through the port C, so that the pressure behind the piston is released and the jet dampers brought into action. The port to the left of the piston valves prevents a dashpot action. It is probable that, although the governor may be set to cut out the jets when the engine exceeds a predetermined speed, yet between the definite jet cut off, or minimum oil pressure, and the maximum oil pressure, there exists a certain range, and it is to regulate or control the oil pressure within this range that the hand setting to the oil governor is provided.

With regard to the self-starter scheme, by means of the lever A on the inlet side of the engine, as shown in the diagrammatic cross section of the engine (fig. 17), all the tappets are

FOREIGN NEWS

FRANCE

Paris, April 13.—Lieut. Sweeney, an American with the French aviation corps, was promoted to captain to-day, and received indefinite leave of absence to "serve America," according to official announcement.

He will leave for the United States at the earliest possible moment.

Sub-Lieutenant Jean Navarre, famous French aviator, is being sought by the police on a warrant charging him with attempted homicide. Since he was severely wounded last June the aviator, according to the *Petit Parisien*, has acted in a most eccentric manner, but was punished lightly in view of the splendid services he had rendered to his country.

Recently he had a dispute with the police, in which he was worsted. That appeared to anger him, and a few nights ago he set out in an automobile and speeded through the principal streets of Paris, knocking down every policeman he saw. As a result five patrolmen were taken to hospitals and several others were severely bruised.

The aviator's friends, the *Petit Parisian* adds, believe that he is not fully responsible for his acts.

Sub-Lieutenant Navarre is one of the most noted of the French aviators. Officially he is reported to have brought down at least eleven German aircraft, and Paris newspapers attribute to him the destruction of nineteen German aeroplanes.

The Aerial League has sent its felicitations and fraternal wishes to the American aero clubs and its salutations to America in honor of American aviators who are in service in France or who have fallen in battle on French soil.

All the information and experience of French and British airmen is to be placed immediately at the disposal of the United States aviation corps by officers detailed by their government to proceed immediately to Washington and become attached to the office of the chief of the army aviation section.

The officers are expected to arrive within a week.

Paris.—The American aviators with the Lafayette escadrille in the French army are hoping that the United States will organize and train more flying squadrons and send them over to help the French. A member of the escadrille in a letter suggests that these squadrons might be named after members of the present squadron who have been killed in action, such as Victor Chapman, Kiffin Rockwell and McConnell.

This letter says that Raoul Lufbery and the French Lieutenant with the Americans each had a combat near St. Quentin a week or so ago, in which Lufbery had fired about forty shots as he dived on a German machine, when his gun broke and he was forced to leave the fight. The Lieutenant lost his opponent in a fog after firing sixty shots.

"On arriving at a new field yesterday," says another letter written on Easter Sunday, "every one was out to-day. Our French Lieutenant had four fights in quick succession. Harold Willis was with him in one of these, having his first battle. Willis attacked and continued firing until something went wrong with his gun.

"Kenneth Marr capsized on landing after his first trip over the lines and tumbled down a railroad embankment. He was not hurt."

Situated within six miles of the first-line trenches in the recently evacuated St. Quentin sector, with the big French guns booming almost under their noses and large calibre Krupp shells occasionally falling nearby, the American aviators are in a position to accomplish great achievements.

The only drawback is the aloofness of the German aviators, who have persistently refused to fly beyond their own lines, thus forcing the Americans to fight them above the anti-aircraft guns. Nevertheless, there have been two enemy machines shot down by their French Lieutenant, Delaage, and several Americans have had brushes with the enemy.

Their French commandant has addressed the American aviators, announcing that since the United States is now an ally the Stars and Stripes will float over the escadrille base and the aviators will be permitted to wear American army uniforms.

Several Americans, particularly those who have been serving for a long time, prefer to continue wearing the French uniform and wish to remain attached to a French escadrille.

"Of course, nobody would refuse to wear the American uniform," said Edward Parsons, explaining their feelings, "but some of us who have been here a long time had rather keep going as we are. Let the new recruits coming over form distinctively American escadrilles, officered by Americans, and wearing the American uniform, but I think the old-timers should be able to transfer to a French escadrille if they wish."

It is expected the American aviators will soon be ordered to purchase American uniforms, although it is understood the Lafayette Escadrille will continue to have a French officer in charge, with Lieut. Thaw. Red, white and blue ensigns will be painted on the Americans' machines.

Dudley Hill, who has been in the United States on furlough, is expected back at the front soon.

GERMANY

"On both banks of the river Somme," the German statement of April 14 says, "strong enemy forces again advanced against our St. Quentin position. The attacks failed under heavy losses, the British leaving three officers and more than two hundred men in our hands."

The statement says that the French exposed historical buildings in Rheims to the danger of damage by the effective fire of the Germans by placing batteries in the vicinity of the structures.

On the western front, it is added, the British and French lost 11 aeroplanes on Thursday and 24 aeroplanes and 4 balloons on Friday.

GREAT BRITAIN

London, April 13.—King George has become Colonel in Chief of the naval and military wings of the Royal Flying Corps "to mark his admiration of the splendid services both wings have rendered since the commencement of the war."

According to an official German statement Lieutenant William Leefe Robinson of the Royal Flying Corps, who was reported missing some days ago, was shot down on April 5, by a German battle aeroplane.

Lieut. Robinson brought down the first Zeppelin to fall on English soil, and was awarded the Victoria Cross.

A site, equipment, and operating funds for an aviation school to train Americans living in England, have been offered to the United States Government, by Barclay H. Warburton of Philadelphia, representing himself and Henry W. Rudd of New York, who is now in London. The grounds are part of Mr. Rudd's estate at Dingfield, just outside of London, and within half a mile of one of the Royal Flying Corps' quarters.

Mr. Warburton told War Department officials that the school would be maintained without cost to the United States until such time as the Government was ready to take it over. He said later that the department had approved of the plan in principle. The plan is designed to give the Americans in England an early chance for active service at the front by quickly developing efficient air squadrons. The Military Attaché of the American Embassy in London would handle applications for membership.

It is hoped that General Sir David Henderson, head of the Royal Training Corps of Great Britain, will detail officers who have seen active service as instructors for the Americans, though it is proposed to have the school itself, as well as such squadrons as are sent to the battle fronts, commanded by officers of the regular branch of the United States Signal Corps. Mr. Warburton probably will serve as a reserve officer.

Dismantling a German machine which was forced to land near the British lines on the Western front. Note the position of the exhaust pipes

Paper Model Aeroplanes in the Making

By A. H. Curtis

So much has been written on the theory of paper aeroplane flying and of the "whys" and the "wherefores" that I think a few notes on the actual construction and flying of these interesting models would not be out of place. It is all very well to lay down a theory, but it is another thing to make the machine prove it in practice. The following is a short description showing exactly how to make a practical paper aeroplane that will not only give a faithful representation of a real machine but will also make good flights.

I find the easiest type to explain is the "Parasol" monoplane.

Firstly, as to the materials required: Some stiff paper (preferably Windsor and Newton's "Drawing Cartridge Paper," which can be had in 6*d*. blocks, 10 ins. by 7 ins., containing 20 sheets, which will serve to make as many models); a small piece of 3/16 in. square wood; some Gloy or paste.

Take a sheet of paper and fold it in half and trace out the outline of the monoplane as shown in Fig. 1.

Now cut this out, rounding all corners and bending where shown so that we have the machine as in the front elevation, Fig. 2.

Now it is necessary that the planes be kept together at the top. For this purpose cut out a rectangular piece of the same paper, 1½ ins. by 6 ins., and after rounding corners, paste this across the top of the planes.

The next thing to fit on is the rudder. Cut out the outline therefore as seen in Fig. 3.

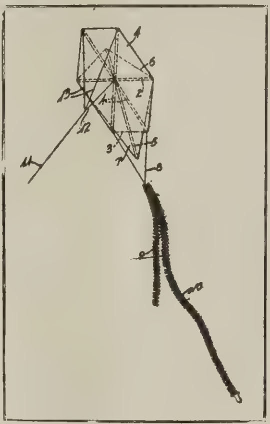
Now paste the shaded portion on both sides and place rudder in position, at the rear of the body, between the two layers of paper.

If the machine was flown in this condition (provided it was weighted), the planes would buckle up. To prevent this take another piece of paper and fold it as before, and cut out shape indicated in Fig. 4, folding where shown and sticking on to the body and wings as in Fig. 5.

This should be fixed on so as to give a very small dihedral angle, *i.e.*, the planes must be practically flat.

(*To be continued*)

Kite Patent



Armando Roa

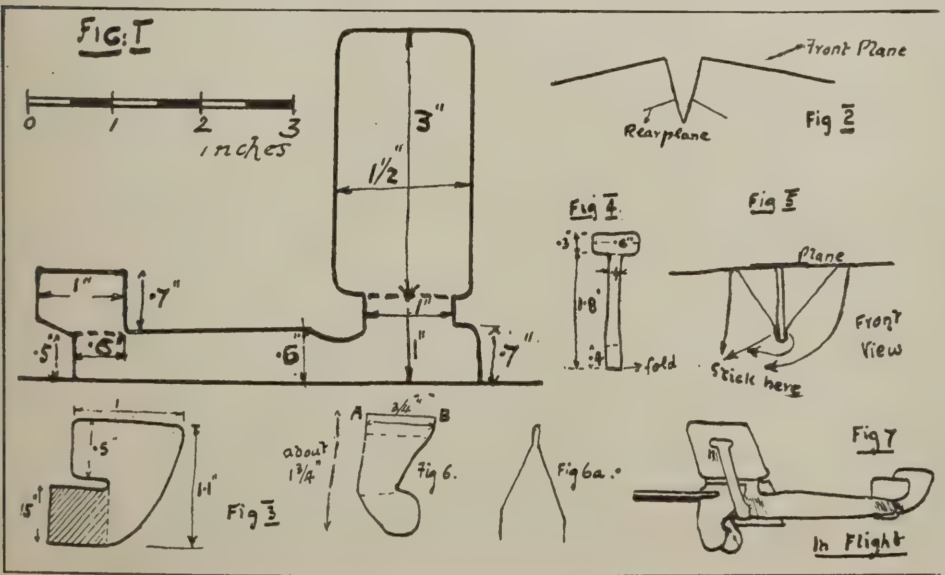
1,214,592. KITE. Armando Roa, New York, N. Y. Filed Aug. 14, 1916. Serial No. 114,712. (Cl. 244—22.)

1. A kite comprising a framework, a covering disposed over the framework, stiffening means carried by the framework and extending below the main body of the kite to form a plane, a double tail secured to the body of the framework, and means for attaching a cord to the framework.

2. A kite comprising a framework, a covering disposed over the framework, stiffening means carried by the framework and extending below the main body of the kite to form a plane, a double tail of unequal lengths secured to the body of the framework, and means for attaching a cord to the framework.

3. A kite comprising a frame having a cover thereon, having its opposite sides of equal length, an attaching member of a length nearly approximating the distance from the center to the upper end of the kite, two attaching members having their ends secured to the upper corners of the frame, a tail suspended from the lower end of the first mentioned attaching member, and a cord secured to the free ends of the last mentioned attaching members.

4. A kite comprising a framework of four intersecting members, one of which projects below the others; a cord disposed around three of the intersecting members, a second cord disposed around the ends of projecting member and one of the other intersecting members, a cover disposed over the framework and the cords, a tail secured to the bottom of the framework, and means for attaching a securing cord to the framework.



The above article is the beginning of a series of articles on the making of paper models

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Right from the Battle-Front.

Pilot, recently returned from Europe—"Yessir, I was so high on one of my flights that when I looked down and saw an uncle of mine far below me, he was so small that he looked like and aunt."

(Hint by the author. Aunt-Ant.)

The High Cost of Living.

Our expert advice in these days of soaring food prices is to biplane food.

A Visit to Mineola in 1909.

Way back in 1909, long before we ever knew that we would some day be thrust into this game of aeronautics, we paid a visit to the aviation field—hopping ground, it should have been called then.

Traveling by motah; no, not *motor—motah,* we arrived at the field one Sunday afternoon about three. Hundreds of automobiles were lined up all around the field waiting for the aspiring, and perspiring, pilots to get their engines tuned up for the flight. Being very young at the time, we could hardly wait for the flying to commence.

Pretty soon, a man dressed like a cross between a Swiss Mountain Climber and a Japanese chauffeur issued mysteriously forth from the sheds, and proceeded to walk slowly upon the field. The babble around the field ceased. We all knew that something was about to happen. What *was* going to happen we did not know, but *something* was going to happen. Trouble was, nothing *did* happen. The man walked around the field a few times and then proceeded to go back into the shed. But at last an aeroplane was pushed upon the field by a gang of about a hundred workmen, all dressed like the first one. Once upon the field they all ran all over in circles, each one with the idea that his mission was of vital importance to the flight which was about to take place. After they had run themselves completely out of breath another queerly dressed man emerged from the shed.

"Ah, there's the aviator," said the man who took all us children down to see the affair.

"How do you know?" we asked him.

"Saw him in the hospital last week."

The aviator proceeded slowly across the field, to the cheering of the multitude. Arriving in the center he paused for a moment, tested the wind, and after shaking hands with a few of his best friends, climbed into the aeroplane.

Two hours later the motor was finally started, and he whizzed across the field. When he had finally attained the terrifying speed of about twenty-five miles an hour, he was seen to jerk frantically at some lever, and the machine gave a short hop, settled down again, something broke, and the whole contraption was wheeled into the shed again.

"Wonderful flight!" said the man next to us.

"Marvelous!" said his campanion.

And we drove home with another illusion sadly shattered.

On With the Dance.

Cholly. Do you know the latest dance?
Percy. No, what is it?
Cholly. The "Panama Canal."
Percy. What's that?
Cholly. Just a series of slides.
Percy. Oh! I always thought it was the "Lock-step."

A. P.

(And the latest dance clothes are probably made with the Culebra cut.)

Undoubtedly Brooklynites.

Newspaper item. "At the start of the fifth inning of the first game in the National League, played between Brooklyn and Philadelphia, Brooklyn was far behind in the score, when two aviators were seen flying over the field. They came down quite near, and evidently seeing the score on the score board, they flew away in disgust."

Songs of the Royal Flying Corps

Ode to the R. A. F. Engine

Eight little cylinders, sitting facing heaven,
One blew its head off—then there were seven.
Seven little cylinders, used to playing tricks,
One warped its inlet valve—then there were six.
Six little cylinders, working all alive,
One got a sooted plug—then there were five.
Five little cylinders, working all the more,
One overworked itself—then there were four.
Four little cylinders, flying o'er the sea,
One shed a piston ring,—then there were three.
Three little cylinders, wondering what to do,
One over-oiled itself—then there were two.
Two little cylinders, very nearly done,
One broke a valve-stem—then there was one.
One little cylinder, trying to pull round seven,
At length gave its efforts up and ascended into heaven.

SO YOU WANTA RESIGN FROM TH' CAVALRY AN' JOIN THE AVIATION SQUAD EH?
YEP, I'M GONNA WRITE TO GENERAL FUNSTON AN' ASK HIM TO TRANSFER ME!
TAKE MY ADVICE AN' STICK TO TH' CAVALRY ETHELBERT OL' TOP!
NAW, I WANT TER BE AN AVIATOR, AN' GET MY NAME IN TH' PAPERS AN' BE TALKED ABOUT!
GOSH! Y'DON'T HAVE TO BE AN AVIATOR TO DO THAT!!
AN' BESIDES THERE'S A BIGGER CHANCE TO RISE —
BUT OH KID, IF YOU FALL, IF YOU FALL, WHAT THEN?
POP

ESTABLISHED 1883

Burgess Primary Training Tractor Type B. P.

This machine was designed by W. Starling Burgess at the request of the United States Army for a primary training tractor aeroplane having a practical side by side seating arrangement with duplicating controls.

This has been accomplished without sacrificing in the least the efficiency or appearance of the machine.

It fills the urgent need found at present in the aviation schools—giving great range of control and allowing the instructor to be at side of the pupil during flight, thereby facilitating instruction.

This has proven very satisfactory in experimental flights as well as in the official trials thru which this machine passed with great success.

THE BURGESS COMPANY
MARBLEHEAD, - - MASS.

Curtiss Model JN4-B Military Tractor

(*Continued from page* 187)

sq. ft. Weight 15½ lbs. It is suported from beneath by a pair of steel tube braces each weighing 2¼ lbs.

From tip to tip the elevators measure 10′-3″. Each 33 13/16″ wide, giving an area of 11 sq. ft each. Weight, each, 8½ lbs. Each elevator flap is attached to the plane by three drop forged hinges.

Vertical stabilizer triangular in shape, has an area of 3.8 sq. ft. Weight, 2½ lbs. The rear edge of this fin is formed by the rearmost vertical fuselage member. Light guys are run from the top of the fin to the rear edge of the stabilizer, continuing underneath the plane to the bottom of fuselage.

The rudder is 37⅜″ in maximum depth. Overall height, 62¾″. Area, 12 sq. ft. Weight, with control braces, 9.75 lbs. The rudder post is of steel tubing. Trailing edge of flattened steel tubing, brazed and attached to the post. Webbing of the rudder is spruce, secured to the framework by means of metal straps brazed to the tubing. Three hinges carry the rudder.

Motor Group

. Motor, Model OX 8-cylinder, Vee, four-stroke cycle, water cooled. Rated horsepower, 90 at 1,400 r.p.m. Bore, 4″; stroke, 5″. Weight per rated h.p., 4.33 lbs

Fuel consumption per hour, 9 gallons Fuel consumption per b.h.p. per hour, .60 lbs.; oil, .03 lbs.

Engine beds are laminated, ash-spruce-ash. They are supported by radiator bracket on front end and by cross-beam at rear end.

The motor complete weighs 390 lbs. Muffler, 20 lbs. 20 gallons of gasoline weighing 124 lbs. are carried in a tank weighing 20 lbs. Tank fittings and piping, 10 lbs. Radiator, 53 lbs. Radiator piping, 7 lbs. Water, 36½ lbs. Propeller, diameter and pitch according to requirement of performance, 25 lbs. Centerline of propeller, 59½″ above ground.

Summary

The loading per square foot of supporting surface is

$$\frac{\text{Gross total load}}{\text{Supporting area}} = \frac{1890}{359.69} = 5.26 \text{ lbs.}$$

The loading per rated horsepower of the motor is

$$\frac{\text{Gross total load}}{\text{Rated h.p.}} = \frac{1890}{90} = 21 \text{ lbs.}$$

FOR SALE: BEAUTIFUL LITTLE LOOPING tractor, practically new, Dep. Control, Anzani motored; will sell motor or plane separately. H. H. Emrick, 330 S. Broadway, Dayton, Ohio.

WANTED AT ONCE: EXPERIENCED AERO-plane Erectors, Fitters, Wing Coverers and dopers to work in a Maryland Factory. State experience and salary expected. Address P. O. Box 93, Hagerstown, Maryland.

DAVENPORT SCHOOL OF AVIATION, IS making special inducements to students as we need men for our new factory. Write today for booklet. School and Factory, Davenport, Iowa.

FIRST CLASS FOREMAN FOR METAL DE-partment aeroplane factory. State experience, salary, etc. Replies held confidential. Box 121, Aerial Age, 280 Madison Avenue, New York City.

FIRST CLASS INSTRUCTOR DESIRES TO associate with reliable concern for instructing or demonstrating. Thoroughly familiar with high powered machines. Would appreciate an interview. Box 144, Aerial Age, 280 Madison Avenue, New York City.

WANTED: OPPOSED, Y, OR RADIAL AIR cooled aeronautical motor, 35 or 45 H.P. Condition, must be perfect. Give detailed specifications. Box 145, Aerial Age, 280 Madison Avenue, New York City.

MODELS—MODEL AEROPLANES, ACCES-sories and supplies. Material suitable for the construction of models that will FLY. Moderate prices. Prompt deliveries. Complete catalog free on request. Wading River Mfg. Co., 550 Macon St., cor. Reid, Brooklyn, N.Y.

LEARN TO FLY, WE OPERATE SCHOOL at Sheepshead Bay Speedway. License Guaranteed. United Eastern Aeroplane Corporation, 1251-1257 DeKalb Avenue, Brooklyn, New York.

NEW AND USED AIRPLANE MOTORS. 14-35 and 55 horse power rebuilt motors guaranteed. Immediate delivery. Prices right. Also "Air-drive" Motors for shallow draft boating. Kemp Machine Works, Muncie, Indiana.

WANTED: AERONAUTICAL ENGINEER for established concern. State experience in full. Confidential. Address Box 143, Aerial Age, 280 Madison Avenue, New York City.

WANTED: TEN 80 TO 100 H.P. AIRPLANE engines (air cooled preferred) from six to twelve cylinders each; must be in good condition; give full particulars. We pay cash. Aero Sleigh Transportation Co., Inc., 541 Payton Bldg., Spokane, Washington.

WANTED: AIRCRAFT DESIGNER THOR-oughly experienced in design and construction of land and water machines. State fully experience and training in engineering, design and flying, also salary expected. Box 141, Aerial Age, 280 Madison Avenue, New York City.

WANTED: DRAUGHTSMEN, DESIGNERS, mechanics and woodworkers; send full particulars as to past and present employment, qualifications, references, salary, etc. Box 138, Aerial Age, 280 Madison Avenue, New York.

WANTED: AIRPLANE AND MOTOR DE-signers, tracers, assemblers, and workmen of all kinds. Give complete details of experience and wages wanted. Egbert B. Cresswell, care of Aerial Age.

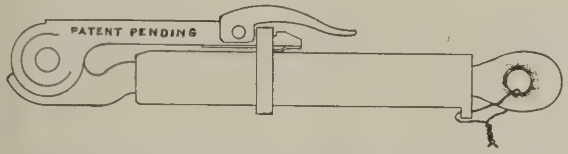
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

Quotations and deliveries on request.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

ALWAYS KEEP THE CHART IN SIGHT

Aeronautic Maps

THE Aeronautic Library has secured the exclusive agency from the Sperry Gyroscope Company for the sale of the Sperry Aeronautic Maps and is now ready to deliver maps New York-Chicago; New York-Newport News; Long Island and vicinity, etc.

Every aviator appreciates the value of an accurate map when making cross-country flights, and the Sperry Aeronautic Maps, and Sperry Map Holder, supply this necessity.

The map can be turned easily in the holder bringing constantly before the aviator a chart of the locality above which he is flying.

The equipment is light in weight and can be fixed to instrument board without interference with the other instruments.

Prices and details on application.

Burgess Primary Training
Tractor Type B. P.

This machine was designed by W. Starling Burgess at the request of the United States Army for a primary training tractor aeroplane having a practical side by side seating arrangement with duplicating controls.

This has been accomplished without sacrificing in the least the efficiency or appearance of the machine.

It fills the urgent need found at present in the aviation schools—giving great range of control and allowing the instructor to be at side of the pupil during flight, thereby facilitating instruction.

This has proven very satisfactory in experimental flights as well as in the official trials thru which this machine passed with great success.

VOL. V NEW YORK, APRIL 30, 1917 No. 7

SEND 5000 AVIATORS TO FRANCE!

ENDORSING a suggestion made by Rear Admiral Bradley A. Fiske, a resolution to train and equip one thousand aviators as soon as possible as the best means to quickly render the most effective service to the Allies, has been adopted by the Governors of the Aero Club of America, and sent to President Wilson, the Chairmen of the Committees on Military and Naval Affairs of the Senate and House of Represnetatives, Secretary Baker, Secretary Daniels, the Council of National Defense and the National Advisory Committee on Aeronautics.

Admiral Fiske's suggestion was made in the following letter to Mr. Alan R. Hawley, President of the Aero Club of America:

"My Dear Mr. Hawley:

"I beg leave to suggest that the Aero Club point out advisability of sending to Europe a large unit of aeroplanes, with trained aviators and appropriate armament.

"One thousand battleplanes, armed with rapid fire guns, bombs and torpedoes, would constitute a combination of power, mobility and control at least equal to that of a hundred thousand soldiers armed with muskets; and that could be more readily transported across the ocean and put to useful work in Europe.

"I am aware of the difficulties of constructing so great a number of large machines; but for such work, the genius of our people and the number and equipment of our factories are especially adapted.

"Sincerely yours,
(Signed) B. A. Fiske,
Rear Admiral, U. S. N. (Retired)."

The Board of Governors' resolution endorsing this suggestion reads as follows:

"RESOLVED: That the Board of Governors of the Aero Club of America endorse the sugegstion of Rear Admiral Bradley A. Fiske that the American Government send to the front as soon as possible a fully equipped aeronautic unit of a thousand aviators, allowing three machines for each aviator, as being the best means in our opinion to quickly render the most effective service to the Allies."

In connection with this it was made public that the officials of the Aero Club of America also endorsed a few days ago the plan submitted by the *London Daily Telegraph* to have the United States concentrate on a plan to send the Allies five thousand aviators as its first military and naval contribution toward assisting the Allies. The *London Daily Telegraph* cabled to New York requesting the opinion of the aeronautical authorities on the subject.

Large Training Camps Could be Established

Mr. Alan R. Hawley, President of the Aero Club of America, gave the following endorsement of the *London Daily Telegraph's* plan:

"Nothing better can be done to assist the Allies than to immediately take steps to train 5,000 American aviators. We have thousands of applications for aviation training from college men who are anxious to join the Army and Naval Reserve to be ready for an emergancy. We also have had a large number of applications from men who would like to join the American Aero Squadron in France or to enter the Royal Air Services. Large aviation training camps could and undoubtedly would be established immediately where students would be given their preliminary training in aviation and in military matters in general. The Aero Club of America has received a large number of offers of extensive tracts of land to be used free of charge for aviation training camps. It has also received liberal offers of funds for establishing aviation training and training aviators in large numbers. But I believe that to give the best results and avoid confusion the training of 5,000 aviators to send to Europe should be undertaken by the American Government. The suggestion comes at the most opportune moment, and you may rest well assured there will be no lack of co-operation in the United States to make the scheme effective. In view of the situation here, one is safe in predicting that of all the forces to be despatched from this side to Europe, the strong probability is that amongst the first would be a large number of representative aero squadrons representing the very best material America can furnish, and all firmed by patriotic enthusiasm at the prospect of flying under the "Stars and Stripes."

Enthusiastic Approval of the Plan

Mr. Henry Woodhouse, member of the Board of Governors of the Aero Club of America, also endorsed the *Daily Telegraph's* proposition as follows:

"I have sounded public opinion regarding the matter of sending a large number of aviators to fight with the Allies and find a general enthusiastic approval of the plan. There will be no trouble to get thousands of volunteers to make up the American Aero squadrons to be sent to Europe. I rather believe that there will be many times more applications than there are wanted. The students from about twenty universities, including Yale, Harvard, Columbia, Princeton, Cornell, Georgia Institute of Technology, are already forming units of the Aerial Coast Patrol, and we have thousands of applications for aviation training on file. There will be no trouble whatever in getting the aeroplanes and equipment needed to train and equip these men, and it would take about ninety days to establish the camps and give the students their preliminary training, including the theory of flight, aerial gunnery, discipline, etc. By that time our American aeroplane factories will be turning out aeroplanes by the hundred. Within six months they will be turning out aeroplanes by the thousands. Everything depends on prompt action by the government reinforced by general public co-operation and with such facilities as we can provide there should be no reason why squadrons fully trained and completely equipped should not leave New York within six months ready for service training, which can only be given on the field of battle."

Aid the Lafayette Aviation Corps

Mr. Augustus Post, Secretary of the Executive Committee of the Aero Club of America, in a speech delivered last Monday evening, prophesied:

"That the first blow struck by Americans on foreign soil would be by aviators sent to aid the Lafayette Aviation Corps, which has already been doing such splendid work at the front." This statement was met with great applause, and it seems the most effective way to send immediate assistance and to strike the strongest blow.

"A canvass has been made of the best fliers in the country," says Mr. Post, "and I understand they have all without exception been willing to volunteer for overseas service, and I also understand that Theodore Roosevelt, who is perfecting plans for the division to be sent abroad, has already made arrangements to include with the men whom he is to lead a fully equipped aerial squadron. I understand officers of the Royal Flying Corps are coming to America to instruct and assist in the training of our air forces and in the development of American machines. The Aero Club of America has received thousands of applications from the best flying material in the country, and the popularity of this branch of the service indicates that there will be no difficulty in securing aviators if the facilities for training are provided. The United States Army are extending their facilities as rapidly as possible for training men and the stations at Mineola and Memphis in the East are taxed to the utmost as well as the private training schools at Newport News and Miami and Palm Beach."

REPORT ON EFFICIENCY OF AMERICAN AEROPLANES MADE CONGRESSIONAL DOCUMENT

THE convincing report submitted by the Advisory Committee on Aeronautics co-operating with the Commander of the Third Naval Reserve Forces has been made a congressional document.

It is known that the authorities who rendered this report had available a vast amount of data of the most authoritative nature regarding the status of aeronautics and the performance of various types in Europe and America and rendered this report after an exhaustive consideration of the situation from every standpoint.

Since the publication of the first report, the Committee has issued a further statement which compares, type for type, the machines constructed in America and in Europe, as follows:

"In the past eighteen months the war has forced a change in the design of aeroplanes; that is, to get greater efficiency and extreme performance, the weights had to be cut down. This, of course, involved greater refinement of detail, and a very considerable reduction of the factor of safety. In fact, factors of safety as low as 3½ instead of the previous 6—8 are being accepted. Further, if these same machines were subjected to what is known as "a sand loading test" (the aeroplane is supported in an inverted position, and sand or shot in bags is piled on the surfaces to approximate the load distribution in flight and increase is made until excessive elongation of parts, in case of tension members, or abnormal deflections are noted, or rupture of any parts occur) it would be found that the factor of safety, thus determined, is far less than the calculated or theoretical factor of say 3½. Further, there is abundant evidence of actual failure of many of these machines in the air, resulting often in fatalities. Cases are on record, particularly with the English machine, of fuselages disrupting in the air under flight loads; tails actually collapsing and breaking off, and even the collapsing of wing structures.

"The French machines, which all along have been sanely developed on the relatively low safety factor basis, are far superior, mechanically, to the general English product, and have much better general attributes and performances.

"Attention should be called, however, to the general excellence of the light weight French motors, which admittedly permit of the great performance of French machines and their superior mechanical qualities. Now, however, motors in America are actually in acceptable production which are the full equal of the best French motors to date. Further, it is of interest to note that a certain engine gives more power than its French prototype, of which it is an exact copy, and all parts interchangeable with the foreign built motor. Some American motors are as good as any abroad. Governor's Island Aero Squadron made about 2500 flights in the past year with only about half a dozen cases of motor trouble.

"Further let us record the fact that we have the talent available in America that can accomplish this task as satisfactorily as the experienced French and English designers and constructors, who can do the job on a real production basis.

"It may be put down as axiomatic in aeronautics that to get performance, one must not see how much you can put on an aeroplane, but how much you can keep off. In other words, in the final analysis, it is low total weight and high horsepower, other things being equal, that gives remarkable performance.

"In the struggle for the supremacy of the air, a premium has been put on speed, and for the sake of speed, machines are turned out with a factor of safety of only two or three. Of course, the factor of safety is of no value if the machine cannot out perform the enemy's machine. But if he will permit American manufacturers to cut down their factor of safety to two or three, and only expect their machines to carry fuel for two hours, we surely can get aeroplanes at least equal to the European machines.

"But we know full well that so long as we have not got to fight off aviators from American skies no one will dare to assume the responsibility of cutting down the present factor of safety of American machines by half. In fact, a minimum factor of say 5 is highly desirable, and will result in most satisfactory performance.

"We who are close to developments and get a lot of information about what they are doing abroad as well as what is being done here, know that American aeronautic engineers can turn out, type for type, machines that are equal to the best European machines. To qualify this statement, there are four types of machines used in number abroad, outside of the large seaplanes in the production of which American manufacturers lead:

"(1) *The training machine:* There are half a dozen manufacturers who can turn out training machines equal to the very best European machines.

"(2) *A machine equipped with motor of between* 120 *and* 200 *H. P. to use for bomb dropping and for spotting artillery fire:* After reading the account of the employment of this type of machine in the raid on the Mauser works, written by one of the members of the Lafayette Corps, who participated, we feel that we have the equivalent of these machins in the two-seater tractors being built by a dozen of manufacturers.

"(3) *The large, slow, bomb carrier,* which is used to carry bombs but is protected during raids by the fast chasers. These machines are either single motored or twin motored. In the raid on the Mauser works they were single motored. In other raids the twin motored have been used. It will be recalled that there never was an order placed for a twin motored land machine in the United States before May 25, 1916, when the Aero Club bought the first twin motored battleplane turned out by the Curtiss Company to send to the Mexican border. Even the European machines, though they carry large loads, have a very slow climbing rate, and no great maximum altitude attribute. Victor Carlstrom flew the first battleplane from New York to Washington on May 25th, with Mr. Alan R. Hawley as passenger, and then the club offered it to the Army, and it was sent to the Mexican border. The Army accepted it in the beginning of June, but it was requested that changes be made in the landing chassis to meet certain conditions to be met at the Mexican border. We asked the Army officers to have the changes made to suit their

(*Continued on page* 233)

THE NEWS OF THE WEEK

Third Yale Air Unit to Train

The third unit of the Aerial Coast Patrol, which was organized a few days ago, with twelve Yale students as members, will begin training immediately at the station recently established by Joseph P. Knapp, president of the American Lithograph Company, at Mastic, L. I.

This is the third patrol unit that has been contributed to the defenses of the eastern seaboard by Yale University. The first was organized some time ago by F. Trubee Davison, son of Henry P. Davison of J. P. Morgan & Co., and Robert Lovett, son of Judge Robert Lovett of the Union Pacific Railroad. This unit, with twenty members, is in training at West Palm Beach, Fla. The second unit, organized by Robert Lovett, G. G. Depew and Frank Goodyear, is training in Buffalo. Other units are being formed in Detroit, Chicago, Marblehead and other cities. The newest addition to the force is expected to be ready for actual service in summer, at which time the aerial patrol system will begin in full swing.

The members of the squadron are: William J. Connors, Jr., Clinton D. Backus, Leslie McNaughton of the Yale crew, Joseph Nagel of the track team, Frank Blossom of the golf team, Capt. Hamilton Gardner of the golf team, David Dunlap, Jack Mitchell, Duncan Forbes, H. Howe, brother of the former football star; and Harold Pumpelly, the gridiron hero who won Yale's game against Princeton three years ago. E. K. Jacquith, the aviator who recently flew from Atlantic City to Miami, will be in charge of the instruction of the students.

Urges Huge Aerial Force to Protect Naval Bases

Major Henry C. Davis of the United States Marine Corps, an expert on scouting flights, has much that is interesting to say concerning aerial defense of isolated naval bases, of which there are many along both the Atlantic and Pacific coasts. Major Davis recommends that air scouts be stationed at all important strategic points. He says:

"The addition of aircraft to the defenses of our naval bases is an imperative necessity.

"Assuming seven hours' endurance, the air scout, at say seventy-five miles an hour, will be enabled to proceed out three hours and return in three hours, leaving one hour for a safety margin. At an elevation of 5,000 feet in clear weather the scout should have a circle of vision the radius of which is approximately seventy miles. He ought to be able also to locate an enemy fleet or a convoy of transports at a distance of 300 miles from the base from which he started. Assuming the enemy speed to be twelve knots—it is more apt to be ten—we have thirty hours' advance notice of his approach.

"The necessity of a much enlarged aerial force for the Marine Corps cannot be too strongly urged."

Offers U. S. Aviation Field

W. B. Strang has offered the aviation field at Overland Park to the United States Government free for use as a training ground for men in the aviation service. There is a steel wireless telegraph station 350 feet high not more than a mile from the field, which Mr. Strang says also might be used in connection with the training. Word has been received from the war department that the offer is being considered.

Atwood with Du Pont Aerial Station

Harry N. Atwood, of the Atwood Aeronautic Company, has been put in full charge of the installation and operation of the new DuPont Aerial Station at Wilmington, Delaware.

Admiral Peary Returns from Pacific Coast

Rear Admiral Robert E. Peary, Chairman of the National Aerial Coast Patrol Commission, returned to Washington April 20th, after a speaking tour of three weeks clear across the country from Washington to San Francisco. He delivered 20 addresses before large audiences in behalf of the Sheppard-Hulbert Bill to create a Federal Department of Aeronautics and a Secretary of Aeronautics. The Washington office of the Aero Club of America reports to AERIAL AGE that scores of telegrams have already been received in behalf of this bill by the entire Congressional Delegations from Illinois, Iowa, Utah and California.

Admiral Peary's principal addresses were in Chicago on April 3. On April 4th, three addresses in Des Moines, Iowa, including one before the joint session of the Iowa Legislature with Governor Harding in the chair, the Bonneville Club of Salt Lake City on April 6, the Aeronautical Society of California in Los Angeles on the 9th, the Navy League of California in San Francisco on the 11th, the Commonwealth Club of San Francisco on the afternoon of the 12th, the University of California on the evening of the 12th, and the San Francisco Press Club on the 13th.

Captive Balloon in Service

The first American captive observation balloon to be manned by a civilian crew went into active training service on Staten Island April 22, with members of the Columbia University Volunteer Signal Corps as its operatives. Major Carl F. Hartman, of the United States Army, one of the few American officers experienced in the work, directed the training. The new unit is the result largely of the efforts of Mrs. Charles A. Van Rensselaer, of No. 130 East Fifty-sixth Street. Under her direction $10,000 has been raised, and with this sum a large eighty-foot sausage balloon has been purchased and other expenses of the unit met.

Training Camp at Marblehead

Boston, Mass.—An aviation base and training camp for airmen of the Naval Reserve force was established recently at Marblehead. The first of 100 officers and men arrived there, and immediately started the work of laying out the new camp. It is the first aeronautical station to be established in the first naval district.

Lieutenant Godfrey L. Cabot, who will direct the activities at the flying school, arrived and immediately started the work of pitching camp. After a consultation with Lieutenant Porter, it was decided that for the present, at least, the men and officers of the aviation squad will be quartered aboard the training ship with the reserve officers and seamen. Flights are expected to start later in the week.

Another detail of the reserves at the Marblehead Neck station has departed for active service. Lieutenant Porter received his second draft order and sent a squad of men for duty aboard ships. The reserves at the camp have two three-hour drill periods daily.

Janney, Steinmetz Receives Order

Philadelphia, Pa.—Janney, Steinmetz & Co., of this city, have received an order for 3,000 hydrogen gas balloon cylinders from the Navy Department. These will be used in the Navy Signal Balloon Service, and are fitted with standard Navy hydrogen high pressure valves.

The meeting of the National Advisory Committee for Aeronautics and aeroplane and motor manufacturers, held in Washington, recently. Some of those in the group are: Dr. Charles D. Walcott, Chairman; Dr. S. W. Stratton, Secretary; Dr. Joseph S. Ames, Dr. Charles F. Marvin, Dr. Michael I. Pupin, Sidney D. Waldon, Dr. W. Christmas, Christmas Aeroplane Company; Mr. G. R. Cockley, International Airship Corporation; Mr. A. H. Flint, Mr. Henry M. Frauenthal, New York Aero Construction Company; Mr. E. F. Gallaudet, Gallaudet Aircraft Corporation; Mr. B. A. Guy, Curtiss Aeroplane Company; Mr. G. H. Houston, Mr. William H. Hutton, Mr. C. M. Keyes, The Curtiss Aeroplane Company; Mr. Glenn L. Martin, Wright-Martin Aircraft Corporation; Mr. H. B. Mingle, Mr. W. B. Judkins, Mr. F. L. Morse, Thomas-Morse Aircraft Corporation; Mr. Israel Ludlow, Mr. C. T. Moore, Seattle, Washington; Mr. F. H. Russell, Burgess Co.; Mr. J. W. Scott, Curtiss Aeroplane Co.; Mr. Henry Harrison Suples, Mr. G. Thomas, Mr. Inglis M. Uppercu, Major C. S. Wallace, Mr. Lee S. Wallace, United Eastern Aeroplane Company; Mr. Harry D. Westcott, New York Aero Construction Co.; Benj. L. Williams, Secretary, Aircraft Manufacturers' Association; Mr. Charles F. Willard, Mr. Samuel Quinn, International Airship Corporation; Mr. Eugene S. Robinson, Mr. Charles B. King, Mr. F. S. Dusenberg, Dusenberg Motor Corporation; Warren S. Eaton, New York Aero Construction Company.

Want Aircraft Materials Inspectors

The United States Civil Service Commission is conducting examinations to fill the position of assistant inspector of engineering material for aircraft. There are at present six positions open, paying from $4.48 to $5.04 per day, and the commission, due to the lack of eligibles and urgent needs of the service, is receiving applications at any time, rating examination papers when received, and will make appointments with the least possible delay. Competitors must have had at least one year's experience as machinist in a factory constructing gas engines for automobile or aeroplane use, or as inspector of aeroplane or automobile engines, or one year's actual experience in flying. In the examination, experience counts 60 points, and education of a technical nature for 40 points out of a total of 100. Applicants are to apply for Form 1,312 to the Civil Service Commission, Washington, D. C., stating the title of the examination.

Harkness Buys Sheepshead Track

The Sheepshead Bay Speedway, New York City, now is in the hands of Harry S. Harkness, its president and chief financial backer. It has been in difficulties for some time. Harkness has purchased the $2,040,000 first mortgage for $1,650,000, and has paid $550,000 in notes bearing his endorsement. Though speedway racing appears to be a thing of the past, at least until the war is over, it is thought that Harkness has made a good investment, as real estate values in the Sheepshead Bay section are thought to be sure to rise.

Detroit as Aviation Center

Detroit—The Aero Club of Michigan has launched a campaign to make Detroit the chief center of the aviation industry in America, and with the immediate object of promoting public interest in air transit and the manufacture of aeroplanes, of bringing a government school to Detroit, of securing an aviation field and of increasing the club's roster to 5,000 or more.

About 800 engineers, manufacturers, mechanics and others accepted application blanks. G. Douglas Wardrop, editor of AERIAL AGE, discussed aeroplanes in Europe, and told of the important part they played in the war.

Motion pictures illustrated every phase of air fighting, and the famous Spad aeroplane was shown, as were photographs of the German Fokker, the French Avions de Chasse and the British triplanes.

Gem May Build Aeroplanes

Grand Rapids, Mich.,—The Gem Motor Car Corp. of this city, has been offered a contract to build 1,000 battleplanes following specifications by French engineers. The contract has not yet been accepted.

Orville Wright in New Aeroplane Companies

Dayton, Ohio. April 14—Orville Wright is listed as an incorporator in two new aeroplane companies formed here this week. The are the Dayton Airplane Co., and the Wright Field Co. The incorporators are the same for the two companies, as follows: Orville Wright, E. A. Deeds, H. E. Talbott and H. E. Talbott, Jr.

Organize Columbia Flyers

The National Coast Patrol Commission has decided to form the 125 students and members of the alumni of Columbia University, who have volunteered for aeroplane service, into the Aerial Coast Patrol Unit No. 4. Clarence Martin, an alumnus, of 52 William Street, organized the Columbia unit, which will have as its instructor Philip Sims, an American aviator who served in the Royal Flying Corps of Great Britain.

The Unit may purchase Howard S. Borden's seaplane for the use of the aviators, and their training ground will be a field on the Shrewsbury River, in New Jersey. It is planned to send six men there next Monday to begin practice. These who do not qualify as aviators may be used as mechanics. More than $6,000 has been subscribed for the use of the Unit.

Miami News

Miami, Fla.—E. H. Holterman, a student of the Curtiss School of Aviation here, finished his course in aviation last week by making a straight thirty-mile flight across country from Miami to Homestead, landing and returning to the starting point, and by so doing becomes automatically a lieutenant in the aerial reserve of the army.

Mr. Holterman, the most proficient pupil of the school, is the first of his class to complete the training and the first graduate from the Miami aeronautical school. Eight of ten others will finish their tests within ten days or two weeks, it is thought.

The flight to Homestead and back was made in one hour and fifteen minutes actual flying time, and fifteen minutes more were passed by Mr. Holterman at Homestead, where Mayor Tatum and several prominent citizens welcomed the first aviator to make a landing in their town.

Sergeant Blake, representing the army, and E. H. Ballard of the aviation company, went to Homestead an hour in advance of Mr. Holterman's arrival and were awaiting him there, when he descended from the low hanging clouds that made his flight somewhat difficult.

Lieuteant Holterman is now awaiting orders from the war department. He has not been informed as to where he will be sent, but is of the opinion that he will be assigned to work as an instructor in the aviation branch of the army.

Princeton Begins Work

Princeton, N. J., April 22—Princeton's aviation school got under way to-day, Lieutenant Edward Kennerson, U. S. A., head instructor, making two flights in a Curtiss aeroplane, the gift of an alumnus.

Four other machines, also the gifts of graduates, are expected to arrive later in the week when instruction will begin.

More than 200 undergraduates have applied for admission to the school. Only about sixty can be accommodated.

Aviation School for Spokane

Spokane, Wash.—A committee of Spokane business and professional men, recently appointed by Mayor Fleming for the purpose of working for a military training camp and an aviation school in the Inland Empire, has left for Coeur d'Alene to meet the recently appointed committee of Coeur d'Alene men.

The Coeur d'Alene committee is composed of F. A. Blackwell, A. A. Crane, A. V. Chamberlain, H. H. Hubbard, Robert H. Elder, Judge R. N. Dunn, C. H. Potts, Judge Flynn, J. C. White and H. Taylor.

"We are anxious to get the co-operation of all people in Washington and Idaho," said Attorney F. C. Robertson of the Spokane delegation, "for the establishment of an aviation school at Coeur d'Alene and a training school elsewhere in the Inland Empire."

S. A. E. Opens Washington Office

Chicago, April 17.—A Washington office of the Society of Automotive Engineers will be opened in the Munsey Building in connection with the Council of National Defense as soon as arrangements can be made. This action, decided upon by the Council of the Society in session here yesterday and today, was brought about by the closer co-operation of the Society with the various Government departments, which work is increasing every day.

The Society is well pleased with the results of its co-operation with the Quartermaster's Department as shown by the specifications of the 1½ and 3-ton military trucks given out this week. The Truck Standards Division of the Standards Committee has assisted the Quartermaster's staff in revising these specifications. Other work, and a great deal of it, remains to be done. It is possible the Society will assist in aviation standardization work, and also in the training of mechanics for aviators as well as in training and supplying mechanics for many other parts of war service.

The Council of National Defense has expressed a willingness for closer assistance by the S. A. E. and the Washington office in this light becomes a necessity. General Manager Coker F. Clarkson, or his assistant Herbert Chase, will probably represent the Society almost continuously in the Washington office.

S. A. E. Summer Meeting to be Held in Washington

New York.—Because of war conditions, the Summer Meeting of the Society of Automotive Engineers, scheduled to be held the last week in June, at Ottawa Beach, Lake Michigan, was called off by the Council of the Society at a meeting held a few days ago in Chicago. An extensive canvass of many connected closely with the activities of the Society showed a general feeling that few of the members could afford the time to spend four days on the east shore of Lake Michigan or at any other place. Each day finds the engineers more and more engrossed in war activities, and correspondingly fewer of the members with spare time for such a meeting.

Instead of four days at Ottawa Beach, it was voted to spend one day on the Summer Meeting,

A group of the American aviators in France, members of the Lafayette Corps, the first unit to take the American flag to the front in Europe.

One of the aviators bombarding New York City with recruiting blanks on "Wake Up America" Day. The demonstration aroused great enthusiasm.

and hold it in Washington, D. C., on Monday, June 25th. Washington was selected because many Government departments are closely associated with the work of the Society.

With one day for a Summer Meeting, instead of three or four, as has been the custom since the start of the Society, the broad program of former years will not be attempted.

Although the Summer Meeting in the sense it has been understood in the past has been called off, the activities of the Society have not been reduced, as such announcement might tend to convey. Instead of the large meeting there will be several smaller and more specific ones.

The tractor engineers, which recently amalgamated with the S. A. E., are confronted with one of the largest problems of the day—the conservation of our agricultural resources and more intensified agriculture. It has been known for a long time that tractor farming means amazingly more than the mere substitution of motor power for animal power. The winter wheat crop situation is a national example of the economic advantage of tractor farming over animal farming. For best winter wheat crops in Kansas, for example, the plowing must be done in July. With horses this month is too hot, and often the ground is too hard. With tractors the heat is no factor. Statistics extending over many years prove the value by increasing yield per acre of tractor farming.

This situation has brought the tractor in international importance and the present demand for increased yield from our farms means perhaps a Government demand for greatly increased tractor production. The lack of standardization in the tractor field as compared with the motor car and motor truck field makes such impossible for a time. The Society faces this problem and its first work in the form of a special meeting will be to get the tractor makers and the Government agricultural interests working together more closely. It is expected that in the near future a meeting to this end will be held. Such meetings will probably take place during the coming summer.

The Summer Meeting of the Standards Committee in Cleveland on May 3d will take on greatly increased importance this year. Besides the 140 men on the various Divisions of the Standards Committee under the direction of Chairman John G. Utz, a call will be made to the members at large of the Society to attend, as the work of standardization is of greatest importance in these days of demand production.

It is possible that a special meeting will be required by the new branch of marine engineering recently amalgamated with the Society and representing motor boat work, such as submarine chasers.

Benoist Activities

The Benoist Aeroplane Company have finished three of their standard 100 H.P., three-passenger boats, which they are now using in the school at Sandusky, and are working on a large 12-passenger boat to be equipped with a single 350 H.P., 12-cylinder Roberts motor. This large machine is to be used in the passenger carrying service between Sandusky and Put-in-Bay. It is contemplated to make a round trip each day during the summer between these two points and one or two round trips a week between Sandusky and Detroit.

Besides these large machines, specifications are going through for a 25-passenger twin-motored Benoist Cruiser to use two of the 350 Roberts. This machine will probably be one of the biggest machines built to date, and will differ to a certain extent from the usual twin-motored machine, inasmuch as both motors are placed in the bow of the boat and a multiplicity of propellers driven from one line shaft, the complete machine being a shaft drive.

Aviators Drop Recruiting Blanks

As part of the "Wake Up America" programme, carried out in New York City, on April 20th, twelve aviators from Governor's Island and Mineola flew over the city, dropping recruiting blanks, urging young men to enlist in some branch of the United States Service. They dropped also petitions for the people to sign calling for universal military training.

Some of the aviators participating were: Bert Acosta, Charles Reid, Captain R. W. Taylor, E. A. Bjorklund, and Captain Martin.

Report on Canada's Flying Schools

Washington.—After six day's stay at the Canadian aviation school, at Camp Borden, Ontario Province, their order for which duty is noted on page 1079 of this issue, Lieut. Col. John B. Bennett, Chief of the Aviation Section, S.C., and Major Benjamin D. Foulois, U. S. A., returned to Washington on April 19th. They reported that the Canadian authorities placed the records of the aviation service at their disposal and gave them all possible assistance in studying the methods of the flying schools.

The Canadian system, much of which probably will be adopted by our aviation corps, is described as follows: Two schools are maintained —one for "cadets" (prospective officers) and the other for "enlisted men," from which ranks are drawn the mechanicians and machinists who form the base and repair forces. On entering the applicant is listed as a "third class mechanic" in each case, the cadet being distinguished by a white band around his cap, a sword-belt in addition to his uniform.

The cadet undergoes one month's instruction in theoretical subjects, at the same time receiving two and one-half hours per day of setting-up exercises. He is then examined and, if passed, goes to "The Wings" where his aviation schooling begins. If unsuccessful in the first examination, the applicant is discharged forthwith. His pay after the first month is that of a private first class.

Instruction in "The Wing" is divided into three classes: Elementary, High and Super-high, corresponding to our "primary," "secondary," and "military," grades. In the first the student receives practical experience in the subjects studied: air stresses, photography, machine gun operation, etc.; in the second he makes short flights with an instructor. He is then examined, both mentally and physically, before passing to the "super-high" course which includes flights without the instructor's assistance or company. Candidates who fail to pass the second class tests are sometimes retained as instructors in the elementary grade but are never promoted to the rank of airmen.

The "ground officers," as those who attend to the detail of office work are termed, are recruited through a separate system and, after three months' instruction, are commissioned as second lieutenants, if successful in their tests. In such cases, they receive the pay of that grade from the date of first enlistment; if they fail in the tests, they are discharged forthwith and receive nothing for the time consumed in preparation. The school maintained by Canada has at present 100 students in the cadet section. The course occupies four months and at its conclusion the students are qualified to start immediately upon active duty.

THE MODERN PAUL REVERE!

Army and Navy News

The following recommendations as "departmental aviation officers" have been made by Brig. Gen. George O. Squier, C.S.O: Col. Samuel Reber, now detailed to Central Department, to Northeastern Department (Boston): Major Leonard D. Wildman, temporarily detailed to office, C.S.O., to Chicago, vice Reber; Maj r Carl F. Hartmann, from the Eastern Departmert, to the Southestern (Charleston).

Capt. Henry H. Arnold, Sig. Corps, U. S. A., commanding the Signal Corps troops in the Canal Zone, is at present in Washington for the purpose of securing certain new equipment for his units.

It is believed that the War Department will accept the offer of Pierre S. duPont, head of the great powder company, and John J. Raskob, the treasurer, to establish an aviation school at the latter's country estate near Wilmington, Del. The offer included also the initial donation of four hydroaeroplanes to be used in the instruction of men who desired to enter the Flying Corps with the intimation that more equipment would be added if circumstances warranted.

Lewis Machine Gun Endorsed

Discussing the value of markmanship, the London *Times* says: "The superiority of the Lewis machine gun to the German weapon is twofold. Like all our guns, big and little, it is a sounder article than its German rival, is less liable to break down, and has a longer life. It is also superior in rate of fire and in power and range."

THE BURGESS TYPE B. P. PRIMARY TRAINING TRACTOR

At the request of the U. S. Army for a primary training tractor, W. Starling Burgess designed this primary tractor having the seating arrangement side by side, allowing the instructor to be at the side of his pupil, and thereby facilitating instruction. Although it was necessary to make the body wider at the cockpit than usual, it has been accomplished with practically no sacrifice to the appearance and at the same time resulting in a fuselage more nearly streamline in plan.

Simplicity of construction throughout has been given consideration, and in experimental and official trials it has proven itself very satisfactory. Large wing area makes the machine comparatively slow and easy for a beginner to handle, and the confidence a pupil gains by sitting alongside of the pilot in his preliminary lessons is an aid to rapid instruction.

The most noticeable feature of the panel construction is the inclined interplane struts. These are not only staggered forward, but also staggered or tilted outward at angles which are increased the further they are from the center of the machine. The wide spacing of the central struts gives a good forward vision.

General Dimensions

Span, upper plane	41′-6″
Span, lower plane	34′-0″
Chord	6′-6″
Area, main planes	437 sq. ft.
Gap	6′-0″
Stagger	1′-9″
Length overall	23′-11″
Motor, Curtiss Model OX	90 H.P.

Planes

Upper plane is in two sections joined at the center, each section 20′-9″ long. Lower plane in two sections attached to body, each section 14′-10″ long. Area of upper plane without ailerons, 219 sq. ft. Lower planes, 182 sq. ft. Ailerons on upper plane sections have an area of 18 sq. ft. each.

Dihedral angle of both planes, ¾°. Angle of incidence, 1¼°. Upper plane staggered 1′-9″ forward of the lower.

Wing curve is the R. A. F. 3. Forward main wing beam centered 9″ back of leading edge. Beams 4′-0″ apart. Trailing edge 21″ from center of rear beam. Ends of the planes are raked at an angle of 16°.

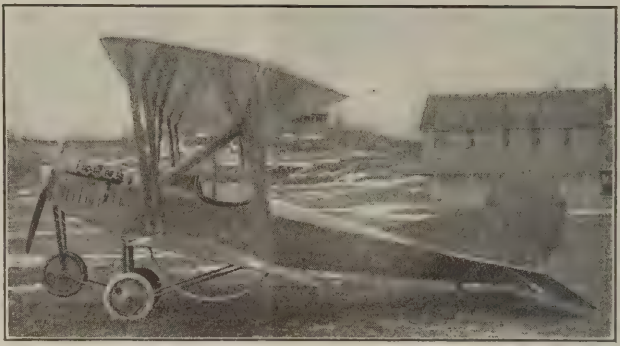
Attachment of the interplane struts on the upper plane is made at the following distances from center: Fuselage struts, 2′-8″ (that is, 5′-4″ apart); Central struts, 9′-1½″ (6′-5½″ from fuselage struts): Outer struts, 16′-9″ (7′-7½″ from central struts). Overhang on either side of upper plane, 4′-0″.

Attachment of interplane struts on the lower plane is made at the following distances from center: Inner edge or root of wing, 2′-1″ (that is, planes spaced 4′-2″ apart); Central struts, 7′-2″ (5′-1″ from inner edge); Outer struts, 14′-5″ (7′-3″ from central struts). Overhang at either side of lower plane, 3′-0″.

Fuselage

Length from front of radiator to tail terminator, 21′-2″. Radiator 27″ wide, 2′-2″ high not including the filler cap. Maximum width of body is at the cockpit, where it is 4′-0″ wide. Depth from bottom of lower longerons of top of upper longerons, 2′-6″. Maximum depth over cowling, 3′-7″.

Upper longerons run back at the level of the line of flight, and 7″ above the center line of propeller. Lower longerons are curved in the forward part, and then run back at an angle to the tail termination, 12″ high.



Side view of the Burgess B. P. Training Tractor.

Landing Gear

The chassis is the 3-wheel type with 26″ disk wheels with 3″ tires. Wheel tread, 5′-4″.

The two main wheels are shock-absorbing, with the axle running in metal guides. The single forward wheel is rigidly mounted.

From the wheels the body is supported by six tubular steel struts, the two forward pairs of which are streamlined with wood. A pair of horizontal rods space the forward wheel hub 3′-1″ in advance of the rear axle.

The tail skid is attached to the body at a point 2′-0″ from the extreme end of the fuselage.

Tail Group

The stabilizing plane is divided, one section at either side of the body. Width 3′-6″. Overall length along rear spar, 14′-0″. Area of the two sections combined, 40 sq. ft.

Elevators or tail flaps, 2′-6″ wide. Distance from tip to tip along trailing edges, 15′-5″. Total Area, 32 sq. ft.

Verticle fin is 6′-0″ long, 2′-6″ high. Area, 15 sq. ft.

Rudder is of the balanced type. Balanced part extends 1′-6″ forward of the pivot; main portion 2′-7″ back of pivot. Maximum height (at rudder post), 5′-6″. Area approximately 13 sq. ft.

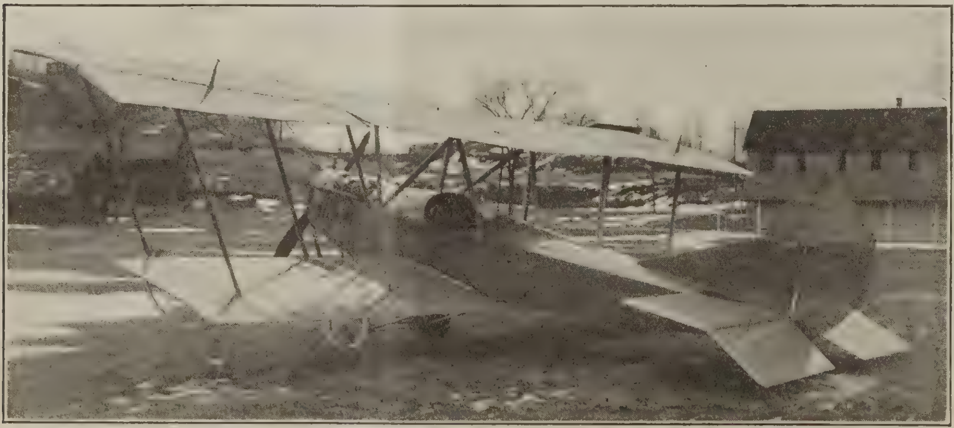
The stabilizer is supported at the leading edge by steel tube braces. Fin and rudder post supported by guys from the rear beam of stabilizer.

Motor Group

The propeller is 7′-9″ in diameter, directly connected to a Curtiss Model OX 90 H.P. V motor. The Model OX has a bore and stroke of 4″ x 5″; it consumes fuel at the rate of 9 gallons per hour.

Ignition is by a high tension, single spark 8-cylinder magneto located at top of crank case and driven off timing gears at front.

Carburetor is the double "Zenith." Each intake supplies one bank of four cylinders through separate manifolds. Lower end of manifolds water jacketed. Auxiliary air intake in manifolds with hand control for altitude adjustment. Carbretor located under front end of motor, and braced by steel struts to crankcase.



Three-quarter rear view of the new Burgess Training Tractor, showing the staggered strut arrangement.

D'ORCY'S AIRSHIP MANUAL

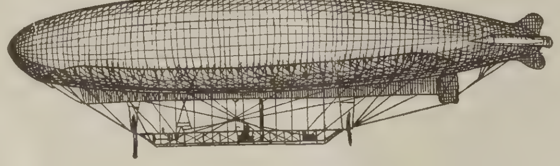
(*Continued from page* 153)

BELGIUM

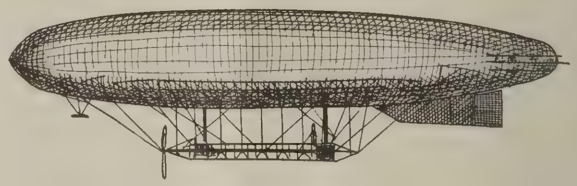
Vivinus Works, Brussels—Builders, to M. L. Godard's designs, of a pressure airship of the keel-girder type. Godard hull. Trim controlled by lifting planes.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (mc)	Power (h.p.)	Speed (km)	Notes
1	**Belgique** (June, 1909)	54.8	9.8	2,700	100	39	Excursion airship of Messrs. Goldschmidt and Solvay of Brussels.—Ballonet: 625 mc. Two Vivinus engines; one tractor and one pusher screws. Best endurance: 2¾ hrs.
1a	**Belgique II** (April, 1910)	65	11	4,000	120	43	Re-built to M. Goldschmidt's designs by the Lembecq Works of Brussels. Car-girder type. Ballonet, heated by engine, 800 mc. One Germain engine; one tractor-screw. Was presented by her owners to the Belgian Army in Sept., 1910; was again re-built and fitted with a hull made by Zodiac and with trimming tanks.
1b	**Belgique III** (May, 1914)	63	11	4,200	120	52	Training airship, Belgian Army. Ballonets: 1,000 mc. Designed endurance: 10hrs.

BELGIUM



Vivinus -"Belgique I" (1909)



Lembecq-"Belgique II" (1910)

BRAZIL

Patrocinio (José de), Sao Paulo—Builder of a pressure airship of the keel-girder type. Carton-Lachambre hull. Height controlled by lifting screws.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (m c)	Power (h p)	Speed (k m)	Notes
1	**Santa Cruz** (1903)	45	21	3,900	40		Experimental airship.—One Buchet engine. On the trials the airship failed to leave the ground and was eventually broken up.

DENMARK

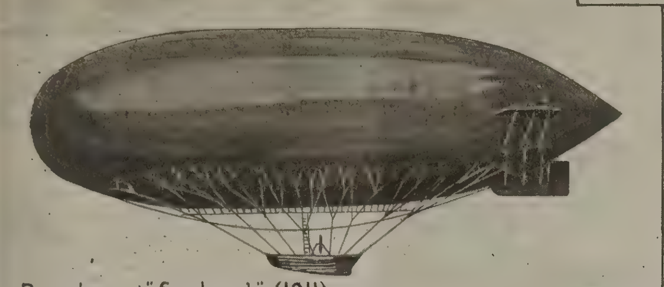
An airship, named **Fionia,** was tested near Copenhagen, in June, 1912. (Photo or sketch and data wanted.)

GERMANY

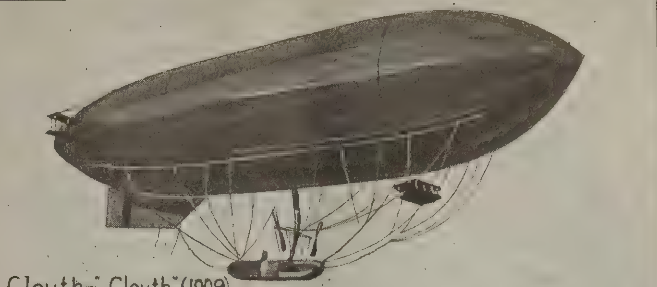
Brucker Transatlantic Flight Expedition, Berlin—Builders of a girderless pressure airship. Riedinger hull; necelle, built like a motor boat, by Lürssen. Trim controlled by lifting planes and a movable weight.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (mc)	Power (h.p.)	Speed (km)	Notes
1	**Suchard** (1911)	60.5	17.2	9,730	220	44	Built for a transatlantic trip from the Canaries to the Lesser Antilles with the help of the trade-winds. Two N. A. G. engines; twin screws. Designed endurance 150 h. with a crew of six.
1a	(1913)	76	17.2	12,000	220	44	One 6 h.p. N. S. U. auxiliary engine, actuating the ballonet blower, the dynamo for wireless telegraphy and the water-ballast winch. Ballonet: 3,600 mc. Was rebuilt after various trials and eventually the transatlantic trip was abandoned.

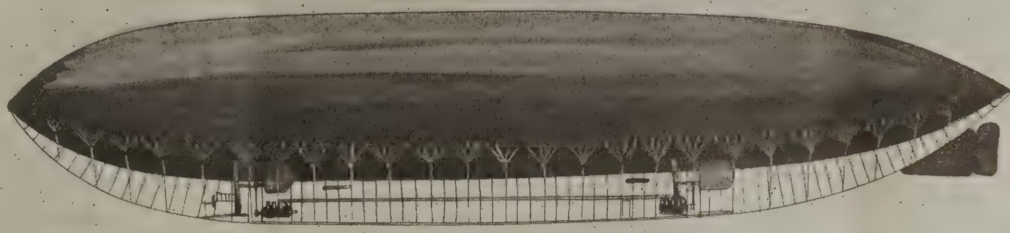
GERMANY



Brucker -"Suchard" (1911)



Clouth-" Clouth"(1909)



D.L.W. -"Veeh" (1911)

GERMANY—(Contined)

Clouth (Luftschiffbau), Cologne-Nippes—Builders of pressure airships of the keel-girder type. Girder consisting of articulated wooden struts; inserted in the bottom of the hull. Trim controlled by lifting planes.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (mc)	Power (h.p.)	Speed (km)	Notes
1	**Clouth** (August, 1909)	42	8.3	1,720	40	35	Excursion airship.—Ballonet: 344 mc. One Buchet engine; twin-screws. After a few trial trips the airship was rebuilt and re-engined.
1a	(1910)	42	8.5	1,850	50	38	One Adler engine; twin-screws. Best endurance: 150 km. in 4½ hrs. (Cologne to Brussels, June, 1910). Was dismantled in 1912, when the Clouth-Luftschiffbau merged with the Luft-Fahrzeug Gesellschaft of Berlin.

Deutsche Luftschiff-Werft, Munich (Bavaria)—Builders, to the designs of Herr Veeh, of a pressure airship of the keel-girder type. Keel of steel tubing, built into the hull and containing the navigation and engine rooms. Trim controlled by lifting planes and trimming tanks. The company was dissolved in 1914.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (mc)	Power (h.p.)	Speed (km)	Notes
1	**Veeh-I** (1911)	70	12.4	6,780	360	60	Experimental airship. — Ballonet: 1,700 mc. Two Schneeweis engines; two pairs of twin-screws. Was tested with one-half the power plant, but did not prove satisfactory and was re-engined and enlarged in 1912.
1a	(July, 1913)	84.5	12.4	9,100	260	68	Two Mercédès engines; two pairs of twin-screws. Designed endurance: 20 hrs. Made numerous trial trips of short duration, but was broken up for lack of funds and sold at auction in 1914.

Milwaukee to Furnish Aviators

Milwaukee, Wis.—It has been announced at the navy recruiting station that Milwaukee will be expected to furnish six aviators for the flying corps. Applicants must pass a stringent physical and mental test, after which they will be sent to Pensacola, Fla., for training. After eighteen months of practice they will be assigned to duty on ship or shore. Aviators must be between 21 and 30 years of age.

The Wisconsin Defense League, which is the outgrowth of the organization which conducted the recent loyalist meeting at the Auditorium, is assisting actively in securing of recruits.

Missouri Aero Corps

St. Joseph, Mo.—An opportunity for young men to enlist in the navy department for aviation duty only is extended in orders received in this city.

It is urged that candidates be carefully selected, and only those who are particularly capable mentally and physically and between the ages of twenty-one and thirty years be accepted. They will be sent immediately to the aeronautic station at Pensacola, Fla., for training.

Applications will be received at the local station, and it is expected that the number desired will be filled quickly.

J. R. Pendleton, secretary of the local civil service board, has been literally flooded with applications for places in the navy yards and arsenals as mechanics. Pendleton received orders to offer opportunity to mechanics, and he has had more than 100 applications.

FACTORS IN THE DESIGN OF HIGH SPEED ENGINES

By E. H. SHERBONDY

The factors are, in simple—

1. Thermo-dynamic efficiency.
2. Volumetric efficiency.
3. Mechanical efficiency.
4. Speed.

Considering each of these factors in turn and commencing with the thermo-dynamic efficiency, this depends initially upon the air cycle efficiency which is dependent solely on the compression ratio and the ratio of specific heats of mixture.

The specific heat of the mixture during combustion increases with an increase in temperature. As a consequence at the higher temperatures the rise in temperature is less per unit of heat.

Heat is lost through the combustion chamber walls and through the cylinder walls. Something like six times the amount of heat passes through the combustion chamber walls than passes through the cylinder walls.

The important heat loss is only that occurring during ignition combustion and expansion. The heat loss during the exhaust is one which is without the designors control.

In running heat balances for internal combustion engines, the results usually include a considerable error in the matter of heat lost to the cylinder walls by reason of the fact that a large percentage of the heat supposed to be lost to the walls during combustion and expansion is in reality lost during the exhaust stroke. Combustion of course is not instantaneous and is seldom complete, and in the majority of engines owing to the localizing of fuel vapor combustion in many cases proceeds during the entire expansion stroke.

The prime cause of this failure is due to the method of feeding the mixture from carburetors, manifolds and valves into the combustion chamber which would not be the case were the engine operating on gas with the proper kind of mixing chamber.

The maximum air cycle efficiency varies with the compression ratio as has been already pointed out from 42.65 per cent for a compression ratio of 4 to 1, to 47.5 per cent for a compression ratio of 5 to 1, to 51.1 per cent for a compression ratio of 6 to 1.

The true heat loss during combustion and expansion in well designed engines varies from something over 17 per cent at 1,000 r.p.m. to slightly under 16 per cent at 3,000 r.p.m. In any event the variation in the heat loss during combustion and expansion is within very narrow limits where there is anything like good charge compounding.

The limiting values of thermal efficiencies are influenced by the mixture of densities or richness, and when this is translated into terms of foot pounds of energy per cubic inch, it may be said that it is impossible to use a wider range than from 37 to 60 foot pounds of energy per cubic inch of mixture. There is a distinctly rapid falling off in the thermal efficiency as we increase the number of foot pounds of energy per cubic inch, as is instanced by the fact that with a compression ratio of 4 to 1 with a mixture of 40 foot pounds per cubic inch density we may arrive at a thermal efficiency of 28 per cent. With the same compression ratio and a mixture density of 60 foot pounds per cubic inch the thermal efficiency falls off to 20 per ecnt. Again, taking the compression ratio of 5 to 1 we find a considerable increase in thermal efficiency rising to 32½ per cent for a mixture density of 40 foot pounds per cubic inch and 23½ per cent for a mixture density of 60 foot pounds per cubic inch.

Going still further in the matter of compression to a ratio of 6 to 1, we obtain a thermal efficiency of 38½ per cent with a mixture density of 40 foot pounds per cubic inch, and 27 per cent with a mixture density of 60 foot pounds per cubic inch.

These mixture densities correspond to a variation in air to fuel ratio of 14.4 to 16.6 to 1.

The mean effective pressures obtained with a mixture density of 45 foot pounds per cubic inch and compression ratio of 5 to 7, amount to 169 pounds per square inch. If we increase the mixture density to 60 BTU per cubic inch, only 45 will be burnt but the thermal efficiency then will fall to 32 per cent and the mean effective pressure wil increase to 173 pounds per square inch.

Again, with a mixture density of 38 foot pounds per cubic inch and thermal efficiency of 32.2 per cent mean effective pressure will be 147 pounds.

These are probably limiting values for gasoline air mixtures where the gasoline has a heat value of 18,500 BTU.

In the matter of volumetric efficiency this depends largely upon the temperature of the mixture as it enters the cylinder, the frictional resistance of the carburetor, intake passages and ports, and the residual pressure of the exhaust products in the clearance space.

Now note that the degree of the temperature nor the bulk of the exhaust gases have any influence on the volumetric efficiency whatever, that is to say, the volumetric efficiency is absolutely independent of the compression ratio provided there is no appreciable exhaust back pressure.

Owing to the fact that the actual absolute volumetric efficiency can never exceed 82.7 per cent, the indicated mean effective pressure becomes somewhat less than in the values given above and will vary from about 125 pounds per square inch, for a 4 to 1 compression ratio, to about 150 pounds per square inch for 6 to 1 compression ratio.

The volumetric efficiency will fall off due to increased velocities through the valves. Neglecting any other frictional work the efficiency will fall from about 78½ per cent for a gas velocity of 100 feet per second through the intake down to about 63¼ per cent for a gas velocity of 240 feet per second through the intake. This is the case where single valves are used and are disposed in the cylinder head. A much lower curve is secured where the valves are carried in pockets.

Under the head of mechanical efficiency, we may also place those lost through the fluid friction and the most convenient method of considering the losses is in terms of mean effective pressure. The bearing friction remains almost a constant during a very wide range of speed. In fact, it always increases slightly up to 5,000 r.p.m. The fluid pumping losses increase more rapidly, varying from a mean effective of about 2 pounds in well designed engines at 1,000 r.p.m. to about 11½ pounds at 5,000 r.p.m.

The next large loss is the loss due to piston friction, which commences at about 5 pounds at 1,000 r.p.m. and increases to about 22 pounds at 5,000 r.p.m. The points between the values given would form a curve which is nearly a straight line. However, upon adding up these respective losses the inclination of the total mechanical loss is seen to vary particularly as the speed passes about 2,000 turns. All of these losses total up at about 35 pounds mean effective pressure at 5,000 r.p.m. However, at 1,000 r.p.m. they are somewhat under 10 pounds.

Considering the case of a 4-cylinder motor with a compression ratio of 5 to 1 and bore and stroke of 4 inches by 6 inches where the reciprocating parts weigh about .2 pound per square inch (which is exceedingly light), we may secure a mean effective pressure on the brake of about 130 pounds up to 3,000 r.p.m. From this point on the curve breaks rather rapidly and if continued to 5,000 r.p.m. we would find a brake mean effective pressure of about 62½ pounds.

The fuel consumption with a mixture density of 45 ft. pounds per cubic inch works out at about .47 pound at 2,000 r.p.m. and rises very rapidly as the speed is increased beyond 3,000 r.p.m., finally reaching a value of over .7 pound at 5,000 r.p.m.

With this same 4 by 6 motor, which has a displacement of 288 cubic inches, the horsepower may be increased from 80 brake horsepower at 2,500 turns when the inlet valve closes 15 degrees after the lower dead center, to about 140 brake horsepower at 3,000 turns when the inlet is closed from 45 to 55 degees late.

The heat balance which will be arrived at with a fairly well designed engine would probably work out with a loss of 52½ per cent to the exhaust, 15.3 per cent loss due to change in specific heat and jacket loss, 4.7 per cent in mechanical loss, and we finally arrive at a net thermal efficiency of 27½ per cent.

It may be said that the efficiencies and mean effective pressures are quite comparable to those arrived at in Diesel engines. In fact, both the thermal efficiency, and as a consequence the fuel consumption in pounds per horsepower hour may be distinctively better in small Otto cycle engines than in small Diesel engines. The mean effective pressures which can be secured in Otto cycle engines are usually in excess of thos secured in Diesel engines, and the specific power per cubic inch of displacement arrived at is and always will remain many times greater than that which can be secured with a Diesel.

THE NEW ALBATROS DE CHASSE

The Albatros Destroyer is known as the Type D. 1, and the example illustrated was shot down about December 1st, 1916, on the British front.

It carries two machine guns, one at each side of the engine. The fabric of the wings, like the fuselage covering, is painted green and red-brown on top, and pale blue below, similar to other German destroyers.

M. Lagorgette in *"L'Aerophile"* states that though the Destroyer is somewhat massive and heavy owing to the weight of its motor, and has not the speed range of the Nieuport, Morane, Spad or Sopwith, it is very handleable and its armament makes it an adversary seriously to be considered.

General Dimensions

Span, upper plane,	8.6 metres
Span, lower plane,	8.05 metres
Chord,	1.62 metres
Plane area,	25 sq. metres
Gap between wings,	1.15 metres
Length overall,	7.3 metres
Motor, Mercedes	170 H.P.

Planes

Angle of incidence near the fuselage, 5.3° (about 145 mm.) which decreases progressively to 4° at the outside rib of the lower left wing and to 2° at the outside rib of the lower right wing, (about 75 mm.)

Lower wings are fixed to the fuselage on a bracket which sticks out beyond the rounding of the monocoque. The upper plane is in a single unit.

The two main spars are placed near the leading edge, the front spar being 11 mm. from the edge and the rear spar 0.8 m. behind it. There is thus a trailing edge with 0.72 m. overhang, in which the ribs are linked together by a third spar, 15 mm. square in section, which is not attached in any way to the fuselage or the cabane.

The spars, like the wings, finish with an outward slant, and are bevelled off sharply on the top side.

Ribs spaced regularly 415 mm. apart in upper plane, and 350 mm. apart in lower plane, except where interplane struts occur, where the rib is displaced owing to the presence of the compression strut, but where the total interval between the two neighboring ribs is still 700 mm.

Ailerons on upper plane, 2.38 m. in span by 0.41 to 0.52 m. chord. Surface, 1 sq. m. each.

The wings can be staggered as desired. Lower wings fixed in relation to the fuselage, but upper plane can be fixed exactly over the lower or can be staggered forward. For this purpose the horizontal tube which forms the summit of the cabane is pierced at each extremity with 5 holes spaced over a distance of 12 cm. within the limits of which distance the 2 bolts fixing the upper plane can be altered in position. This arrangement is probably made so as to alter the center of pressure to allow for alteration in the size and weight of the motor used, and also possibly for the weight of the pilot. The c.p. is thus shifted longitudinally and the weights correctly adjusted instead of adopting the usual method of merely changing the angle of the tail.

There is a single pair of interplane struts of streamline section on each side of the fuselage. They are parallel to one another, and not diverging.

Fuselage

Length, 6.5 m.; maximum depth, 1.5 m.; maximum width, 0.93 m. There are six longitudinals, two of which are smaller than the others and are fixed half way up the sides. The two upper longerons are not exactly above the lower ones, but are distinctly wider apart. All longitudinals are of spruce except the fore part of the two lower ones, which are of ash as far back as the pilot's seat, where they are 40 mm. deep and 30 mm. thick. They are wrapped spirally with fabric.

To the longerons are fixed simple transverse frames without cross struts. They form the body of the monocoque, and onto them are nailed the three-ply sheeting which covers it. These frames, which are reinforced where they join the longerons are composed of simple laths 20 mm. by 10 mm., rounded on their interior face. Where the tail plane and the fin are fitted in, there are two transverse formers in thicker wood.

Tail Group

The fuselage terminates in a T shape which gives an anchorage horizontally to the tail controls, and because of the enormous thickness of the fixed tail planes (150 mm.), and the fitting of the vertical fin forward, where the fuselage is still very thick, the usual strengthening brackets on the fixed tail are done away with.

In its two parts, without counting the interposed portion of the fuselage, the tail plane has a surface of 1.4 sq. m. There is no incidence angle on the tail plane.

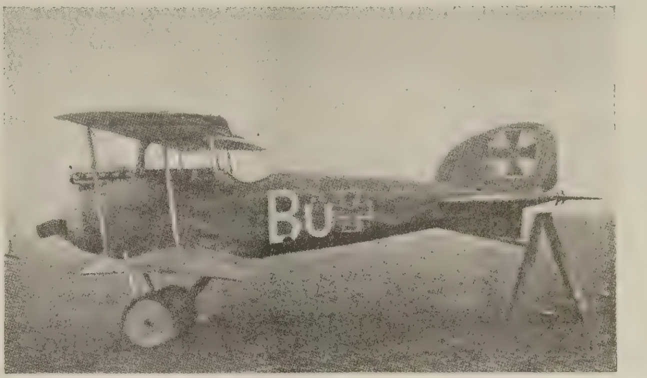
The elevator is a single unit, balanced by a small triangular part projecting forward on the elevator hinge at either end. Surface, 1.1 sq. m., including **0.08 sq. m. of the balanced section.**

Fin surface 0.8 sq. m. (0.55 above and 0.25 below). Their framework, like that on the tail plane, is of wood. The elevator and rudder frames are built of tube.

Balanced rudder, area 0.55 sq. m., including the balanced portion of 0.08 sq. m.

Landing Chassis

Wheel track, 1.8 m. Cross bracing cables are between the rear struts. There is no claw brake.

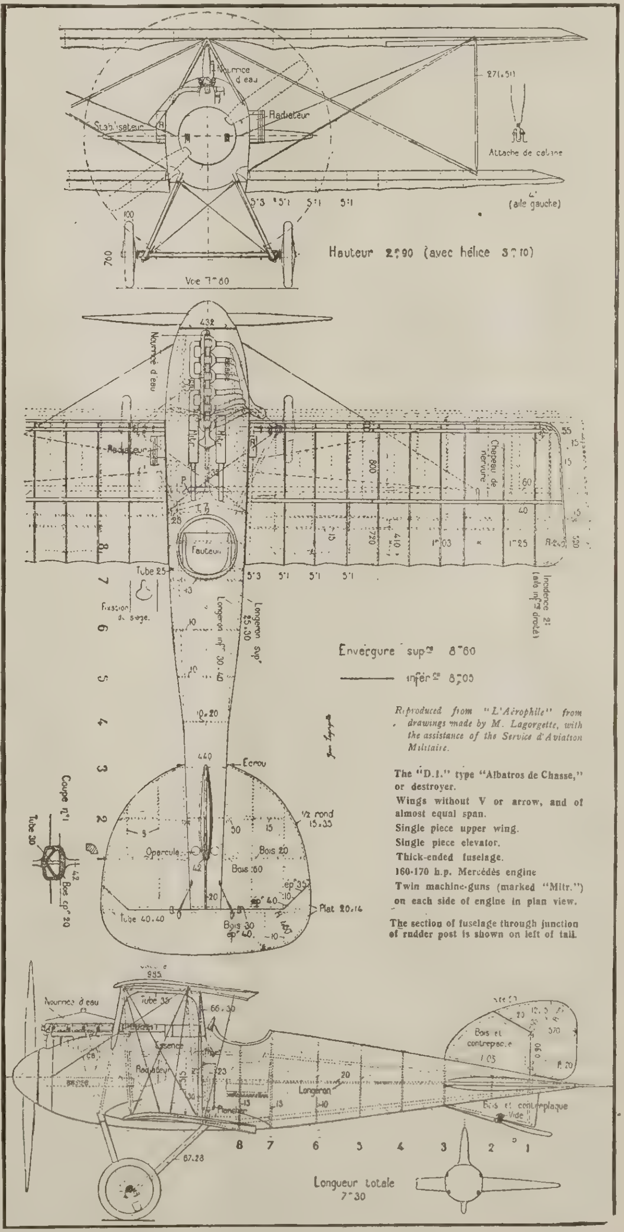


The German "Spad."

Motor Group

Motor, 6-cylinder Mercedes, which gives 170 H.P. at 1,450 r.p.m. The propeller is 2.8 diameter.

The exhaust pipe is pointed obliquely backward and downwards. The two radiators are of a new form, fixed one on each flank of the fuselage outside, one being thicker horizontally than the other. Their position necessitates a gravity tank, flat and triangular, which is located above and to the left of the camshaft. The air pump, with machine gun in front, is fixed above the front of, and not behind, the camshaft.



Reproduced from "L'Aérophile" from drawings made by M. Lagorgette, with the assistance of the Service d'Aviation Militaire.

The "D.I." type "Albatros de Chasse," or destroyer.

Wings without V or arrow, and of almost equal span.

Single piece upper wing.

Single piece elevator.

Thick-ended fuselage.

160-170 h.p. Mercédès engine

Twin machine-guns (marked "Mitr.") on each side of engine in plan view.

The section of fuselage through junction of rudder post is shown on left of tail.

METHODS OF MEASURING AIRCRAFT PERFORMANCES*

By CAPT. H. T. TIZARD, R. F. C.

(*Continued from page* 117)

The aneroid being what it is, one soon comes to the conclusion that the only way to make use of it in aeroplane tests is to treat it purely as a pressure instrument. For this reason it is best to do away with the zero adjustment for all test purposes and lock the instrument so that the zero point on the height scale corresponds to the standard atmospheric pressure of 29.9 ins. or 760 mm. of mercury. Every other height then corresponds to a definite pressure; for instance, the locked aneroid reads 5,000 ft. when the atmospheric pressure is 24.88 ins., and 10,000 ft. when it is 20.70 ins., and so on. If the temperature is noted at the same time as the aneroid reading, we then know both the atmospheric pressure and temperature at the point, and hence the density can be calculated, or, more conveniently, read off curves drawn for the purpose. The observations necessary (after noting the gross aeroplane weight and net or useful weight carried) are therefore: (i) Aneroid height every 1,000 ft.; (ii) time which has elapsed from the start of the climb; and (iii) temperature. To these should be added also (iv) the air speed and (v) engine revolutions at frequent intervals. The observed times are then plotted on squared paper against the aneroid heights and a curve drawn through them. From this curve the rate of climb at any part (also in aneroid feet) can be obtained by measuring the tangent to the curve at the point. This is done for every 1,000 ft. by aneroid. The *true* rate of climb is then obtained by multiplying the aneroid rate by the correction factor corresponding to the observed temperature. These true rates are then plotted afresh against standard heights, and from this curve we can obtain the rate of climb corresponding to the standard heights, 1,000, 2,000, 3,000, etc. Knowing the change of rate of climb with height, the time to any required height is best obtained by graphical integration. The table below gives the results of an actual test.

At least two climbing tests of every new machine are carried out up to 16,000 ft. or over by aneroid. If time permits three or more tests are made. The final results given are the average of the tests and represent as closely as possible the performance on a standard day, with temperature effects, up and down currents and other errors eliminated.

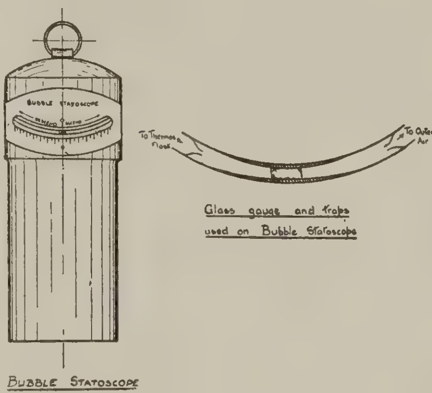
If we produce the rate of climb curve upwards it cuts the height axis at a point at which the rate of climb would be zero, and therefore the limit of climb reached. This is the "ceiling" of the machine.

SPEEDS

His 16,000 ft., or whatever it is, reached, the flyer's next duty is to measure the speed flying level by air speed indicator at regular intervals of height (generally every 2,000 ft.) from the highest point downwards. To do this, he requires a sensitive instrument which will tell him when he is flying level. The aneroid is quite useless for this purpose, and a "statoscope" is used. The principle of this instrument is really the same as that of a climb meter. It consists of a thermos flask connected to a small glass gauge, slightly curved, but placed about horizontally (see Fig. 2). In this gauge is a small drop of liquid, and at either end are two glass traps which prevent the liquid from escaping either into the outside air or into the thermos flask. As the machine ascends and the atmospheric pressure being smaller, and the pressure in the flask being higher than the external pressure, the liquid is pushed up to the right hand trap, where it breaks, allowing the air to escape. On descending the reverse happens; the liquid travels to the left, breaks, and air enters the flask. When flying truly level the drop remains stationary, moving neither up nor down. The instrument is made by the British Wright Co.

The flyer or the observer notes the maximum speed by the air speed indicator—*i. e.*, the speed at full engine throttle. At one or more heights, also, he observes the speeds at various positions of the throttle down to the minimum speed which will keep the machine flying at the height in question. The petrol consumption and the engine revolutions are noted at the same time, as well, of course, as the aneroid height and temperature. Accurate observation of speeds needs very careful flying—in fact much more so than in climbing tests. If the air is at all bumpy observations are necessarily subject to much greater error, since the machine is always accelerating and decelerating. The best way to carry out the test seems to be as follows. The machine is flown first just down hill and then just up hill and the air speeds noted. This will give a small range between which the real level speed must lie. The flyer must then keep the speed as steadily as possible on a reading midway between these limits, and watch the statoscope with his other eye. If it shows steady movement, one way or the other, the air speed must be altered accordingly by 1 m.p.h. In this way it is always possible at heights where the air is steady to obtain the reading correct at any rate to 1 m.p.h., even with light machines, provided always sufficient patience is exercised. The r.p.m. at this speed are then noted.

FIGURE 2



BUBBLE STATOSCOPE

Glass gauge and traps used on Bubble Statoscope

FIGURE 3.

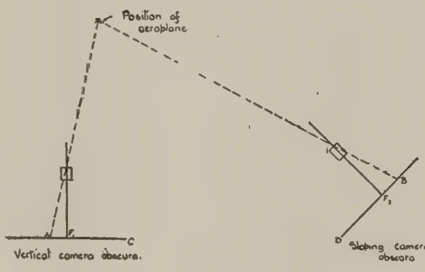


FIGURE 4

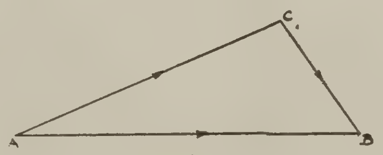


A.B represents the measured speed of the aeroplane on the ground.

CB on the same scale represents the Velocity and direction of the wind.

Therefore AC represents the real speed of the aeroplane through the air.

One difficulty, however, cannot be avoided. If at any height there is a steady up or down air current, then though the air may appear calm, *i. e.*, there may be no "bumps," the air speed indicator reading may be wrong, since to keep the machine *level* in an up current it is necessary to fly slightly down hill relatively to the air. Such unavoidable errors are, however, eliminated to a large extent by the method of taking speeds every 2,000 ft., and finally averaging the results.

We must now consider how the true speed of the aeroplane is deduced from the reading of the air speed indicator. It is well known that an air speed indicator reads too low at great heights—for example, if it reads 70 m.p.h. at 8,000 ft. the real speed of the machine through the air is nearer 80 m.p.h. The reason for this is that the indicator, like the aneroid, is only a pressure gauge—a sensitive pressure gauge, in fact, which registers the difference of pressure between the air in a tube with its open end pointing forward along the lines of flight of the machine, and the real pressure (the static pressure) of the external air. This difference of pressure is as nearly as we can judge by experiment $= \frac{1}{2} \rho V^2$ (where ρ is the density of the air and V the speed of the machine), provided that the open end of the tube is well clear of wings, fuselage, etc., and so is not affected by eddies and other disturbances. Now, assuming this law, air speed indicators are graduated to read correctly, as I have said above, at a density of 1.221 kgm. per cubic metre, which we have taken as our standard density and called "unity." It corresponds on an average to a height of about 800 feet above sea level.

Then suppose the real air speed of an aeroplane at a height of "h" feet is V m.p.h., and the indicated air speed is 70 m.p.h., this means that the excess pressure in the tube due to the speed is proportional to 1×70^2,

$$\text{or } \rho \times V^2 = 1 \times 70^2,$$

where ρ is the density at the height in question, expressed as a fraction of the standard density. To correct the observed speed, we therefore divide the reading by the square root of the density. Thus, observation of the maximum speed of an aeroplane at a height of 8,000 ft. by the locked aneroid gave 80 m.p.h. on the indicator, the temperature being 31° Fahr. From the curve we find that the density corresponding to 8,000 ft. and 31° is 0.85 of standard density. The corrected air speed is therefore:

$$= \frac{80}{\sqrt{.85}} = 86.7 \text{ m.p.h.}$$

This "corrected" air speed will only be true if the above law holds, that is to say, if there are no disturbances due to the pressure head being in close proximity to struts or wings. It is always necessary to find out the magnitude of this possible error, that is, to calculate the air speed meter, and the only way to do this is to measure a real air speed at some reasonable altitude for easy observation of the aeroplane by actual timed observations from the ground, and from these timed results check those deduced from the air speed indicator readings. This calibration is the most important and difficult test of all, since on the accuracy of the results depends the accuracy of all the other speed measurements. It can either be done by speed trials over a speed course close to the ground, or when the aeroplane is flying at a considerable height above the ground. In the Testing Squadron we have always attached much more importance to the latter method, mainly because the conditions approximate more to the conditions of the ordinary air speed measurements at different heights, and because the weather conditions are much steadier and the flyer can devote more attention to flying the machine at a constant air speed than he can when very close to the ground.

One method is to use two camera obscuras, one of which points vertically upwards and the other is set up sloping towards the vertical camera. At one important testing center the cameras are a mile apart, and the angle of the sloping camera is 45°. By this arrangement, if an aeroplane is directly over the vertical camera it will be seen in the field of the sloping camera if its height is anywhere between 1,500 and 15,000 feet, although at very great heights it would be too indistinct for measurements except on a very clear day. The height the tests are usually carried out is 4,000 ft. to 6,000 ft.

The aeroplane is flown as nearly as possible directly over the vertical camera and in a direction approximately at right angles to the line joining the two cameras. The pilot flies in as straight a line and at as constant an air speed as he can. Observers in the two cameras dot in the position of the aeroplane every second. A line is drawn on the tables of each camera pointing directly towards the other camera, so that if the image of the aeroplane is seen to cross the lines in the one camera it crosses the line in the other simultaneously. From these observations it is possible to calculate the height of the aeroplane with considerable accuracy; the error can be brought down to less than 1 part in a 1,000 with care. Knowing the height, we can then calculate the speed over the ground of the aeroplane by measuring the average distance on the paper passed over per second by the image in the vertical camera. If x inches is this distance, and f the focal length of the lens, the ground speed is $x \times h / f$ feet per second.

---

* Lecture delivered before Aeronautical Society of Great Britain.

It is necessary to know also the speed and direction of the wind at the height of the test. For this purpose the pilot or his observer fires a smoke puff slightly upwards when over the cameras, and the observer in the vertical camera dots in its trail every second. The height of the smoke puff is assumed to be the same as that of the aeroplane—it probably does not differ from this enough to introduce any appreciable error in the results. The true speed through the air is then found graphically as shown in Fig. 4. Here the length AB represents the ground speed of the aeroplane as measured in the camera and CB represents on the same scale the velocity and direction of the wind. The length AC represents, also on the same scale, the true air speed of the machine.

The tests are done in any direction relative to the wind, and generally at three air speeds, four runs being made at each air speed.

The advantages of this method are:

(1) Being well above the earth the pilot can devote his whole attention to the test.

(2) Within reasonable limits any height can be chosen, so that it is generally possible to find a height at which the wind is steady.

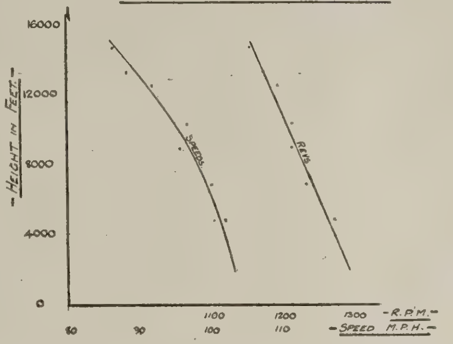
(3) It does not matter if the pilot does not fly along a level path so long as he does so approximately. What is more important is that he should fly at a constant air speed.

(4) It is not necessary that there should be any communication between the two cameras, although it is convenient. The two tracks are made quite independently, and synchronized afterwards from the knowledge that the image must have passed over the center line simultaneously in the two cameras.

The main disadvantage is that somewhat elaborate apparatus is necessary, but this is of not much importance in a permanent testing station. There are often periods in war time, however, when an aeroplane has to be tested quickly, and low cloud layers and other causes prevent the camera test from being carried out. It is then necessary to rely on measurements of speeds near the ground for the calibration of the air speed indicator. In this method the aeroplane is flown about 10 ft. off the ground, and is timed over a measured run. There are two observers, one at each end of the course; when the aeroplane passes the starting point the observer sends a signal and starts his stop-watch simultaneously; the second observer starts his stop-watch directly he hears the signal, and in his turn sends a signal and stops his watch when the aeroplane passes the finishing point.

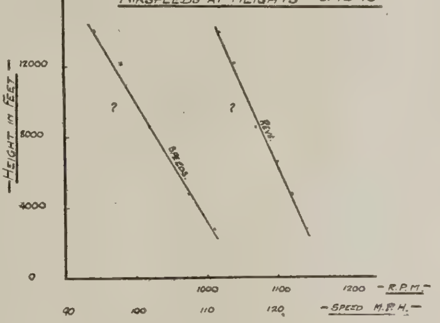
-FIGURE 5-

-AIRSPEEDS AT HEIGHTS 27. 12. 16-



-FIGURE 6-

-AIRSPEEDS AT HEIGHTS 9. 12 16-



By this double timing, errors due to the so-called "reaction time" of the observers are practically eliminated, for the observer at the end of the course tends to *start* his watch late, while the first observer *stops* his late. The mean of the two observations gives the real time. Four runs, two each up and down the course, are done at each air speed, the pilot or his observer noting carefully the average air speed during the run. Observations of the atmospheric pressure and temperature from which the density can be obtained are also taken. The average strength and direction of the wind during each trial are noted from a small direct reading (or recording) anemometer and the speed corrected in the same way as in the camera tests. If there is a strong cross wind the aeroplane may have to be pointed at a considerable angle to the course, and this makes the test a very difficult one to carry out well. Generally speaking, it is only reliable when the wind is quite light, not more, at any rate, than 10 m.p.h. Even this is too strong if it is a cross wind.

A further difficulty is that at high speeds, over 100 m.p.h., an aeroplane may take quite a considerable time to accelerate up to a steady speed, and so it must fly level for a long distance each end before reaching the actual course. At the testing station previously alluded to the course is a mile long, and there is a clear half-mile or more at each end, but it is doubtful whether even this distance is enough for the machine to attain steady speed before the starting point. Finally, the flyer of a single-seater is generally too busy watching the ground to do more than glance at his air speed indicator more than a few times during the run. Doubtless it would be better in such a case to use some form of recording air speed instrument, although then other difficulties would arise.

Having got the true air speed from camera or speed course tests, and knowing the density at the height at which the test was carried out, we obtain what the air speed indicator should have read by multiplying the measured air speed by the square root of the density. By comparing this with the actual reading of the indicator we obtain the necessary correction. The whole procedure may be shown best by a table giving part of the results of a camera test made at the beginning of the year.

A summary of the complete speed tests may now be given. Firstly, the air speed and engine revolutions are noted flying level at full throttle every 2,000 feet approximately by aneroid. From the aneroid reading and temperature observation at each height the density is obtained. The reading of the air speed indicator is then first

15,000	86.0 "	1,160

FOREIGN NEWS

ARGENTINA

Buenos Ayres—The Argentine military aviator Corporal Fels, who has made some notable records in flying, has decided to enlist in the Aviation Corps of the American army. Fels has asked permission of the War Minister, who is said to be favorable to the project.

AUSTRIA

The official statement of the Austrian War Office for April 21 is as follows:

In connection with Entente air raids on suburbs of Trieste, which caused no considerable damage, a squadron of Austrian naval aeroplanes before daybreak on April 20 dropped bombs on the military works of San Canziano, southwest of Gorizia.

A large fire was caused, the statement adds, and all the machines returned safe.

FRANCE

Paris—The French Lieutenant attached to the Lafayette Escadrille, composed of the American aviators with the French army, told the correspondent of *The Sun* that he had charge of the investigation of the circumstances of Edmond Genet's death.

The American's aeroplane apparently had been damaged by German anti-aircraft artillery fire, he said. Genet tried to return to the escadrille's quarters, but his machine was so damaged that it fell near Ham, within the French lines. The body was found and buried in the Ham cemetery.

The Lieutenant was deeply affected by Genet's death. "He was our Benjamin, beloved by us all," he said. "Our only reproach against him had been his reckless daring, which was greater even than McConnell's. Had he lived, he would have accomplished great things."

German aviators are using the adoption of a special escutcheon as the insignia of the American Escadrille on their airplanes, in an attempt to deceive the Allies as to the true nationality of their own airplanes.

Heretofore all the Allies' machines—British, Belgian and French, as well as American—had painted on their planes a red circle inclosing a white circle, with a blue ball in the center. Since the American insignia was adopted providing for a blue star instead of the blue ball, the Germans changed their insignia from the large black cross to a small one in the center of the ring, thus hoping the Allied aircraft will not fire upon them, and that Allied machines may approach them, thinking them friendly.

Several German machines so marked already have been brought down, as the Allied aviators and gunners distinguish the enemy machines by construction details, disregarding the painted insignia.

Paris, April 22—Reports reached Paris today that William Dugan, an American aviator who has been at the front flying with the American Escadrille for about a month, is missing.

Dugan started out on reconnaissance work in the neighborhood of St. Quentin yesterday and failed to return before dark. There is a chance he alighted on the field of some other escadrille, or even strayed into the British lines adjoining toward the northward.

He hails from Rochester, N. Y., and early in the war came over as an ambulance driver for the American Ambulance Hospital. This was not active enough for him, however, and before long he enlisted in the Foreign Legion, volunteering, after nearly two years' service in the trenches, for the aviation service.

GREAT BRITAIN

London, April 18—In the House of Commons today it was suggested that the British Government should appeal to the United States to concentrate on the construction of aeroplanes. John L. Baird, representative of the Air Board in the House of Commons, replied:

"The subject already is under consideration by the Government of the United States."

British Headquarters in France, April 22—Here is the record of a single flight of one of our airmen, made within a few days. I have cut out only the names and other small details which might conceivably be useful to the enemy. Otherwise the record is precisely as the aviator wrote it:

"When our machines were attacking Cambrai I attacked a hostile aviator at a height of about 7,000 feet. I saw that I had hit his engine as we closed and half looped to one side of him. Then he dived, with a long trail of blue smoke. I dived after him to about 4,000 feet and fired fifty rounds into him, when he went down absolutely out of control. I watched him spinning down 1,000 feet, his trail of smoke increasing.

"I was immediately attacked by three enemy machines, which drove me down to a height of only 200 feet. We were firing on one another whenever possible. When at last I got into a good position I attacked one of them from above, having another on my right. I closed on the latter, turning in on him so close that I could actually get a sight on the pilot's head. I saw one of my bullets strike his head, and the machine then simply heeled over and fell to the ground. The other two machines cleared off.

"Having lost sight of the other machines I decided to fly home very low, about 200 feet. A troop of German cavalry going east along a small road halted and fired at me, and also several machine guns opened fire on me from the ground.

"After going west for about five minutes I was again attacked by an enemy single seater. As he approached I rocked my machine until he was within fifty yards. Then I sidelooped over him and fired a short burst at him. He seemed to clear off, and then attacked me again. These operations were repeated several times with slight variations in the way I looped over him until, within about five minutes of the time of crossing the line (flying against a strong wind) when he was about 150 yards behind, I looped straight over him.

"Coming out of the loop, I fired a good long burst and saw where I hit the pilot in the back, just over the edge of the cockpit. He immediately dived straight to the ground.

"I then went over German trenches filled with soldiers. I was fired on by machine guns, rifles and small field guns. There was a lot of artillery firing going on, and many of our shells were bursting about the German trenches, somewhere in the vicinity of the Cambrai road. I saw many small companies of infantry and cavalry, going east along the small roads, but noted no convoys or movements of artillery.

"I landed at the first aerodrome I saw, for my machine was badly shot about."

During the battle, besides the daily job of observation of the enemy's guns and positions, our airmen continually fly far into the enemy's country. In the last few days alone they have dropped twenty-seven tons of explosives on enemy stations, depots and stores and positions of all kinds. They have gone down close to earth and sprayed the German trenches and roads with machine guns.

ITALY

The Italian account of the sea and air battle near Venice on April 17 says:

"A number of aeroplanes, aided by torpedo boats, approached Venice on April 17 in order to effect a reconnaissance in force. A rapid counter attack by Italian and French aeroplanes and the fire of our batteries prevented the enemy machines from flying over the city. In a series of aerial duels one enemy aeroplane was shot down. Two Italian hydroplanes have failed to return to their bases."

JAPAN

(From the *Japan Times* of March 17)

By way of expressing its deep sorrow over the tragic death of Captain Sawada, military aviator, which took place a few days ago at Tokorozawa, the Imperial Aviation Association has presented the sum of 500 yen to the family of the lamented military aviator.

It is also reported that the Association, in the name of Marquis Okuma, the President, has sent a telegram of sympathy to Lieutenant-Commander (not Major, as previously reported) Isobe who, as reported, sustained injuries at the French front recently.

Opinions are now gaining ground among the military authorities advocating the establishment of an official aviation school in view of the present aerial situation in Europe, reports the Tokyo *Mainichi*. The authorities are reported to be making investigations for this purpose.

MEXICAN PILOTS AND AEROPLANES AT THE NATIONAL AERODROME AT VALBUENA, MEXICO

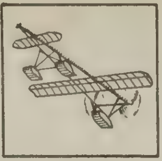
MODEL NEWS

Edited by G. A. Cavanagh



Paper Model Aeroplanes in the Making

(*Continued from page* 195)

Now we are ready for the chassis and weight. The writer has found that a visiting card is very serviceable for the former. Fold it in half and cut out any form somewhat similar to that shown in Fig. 6, and bend as in 6*a* (front elevation).

The two sides can now be separated by cutting along the fold from A to B.

Next cut off a piece of 3/16-in. square wood, 3 ins. long, and make a slit in the centre of one end ¾ in. long, and after placing chassis in position (one half on each side of body), fix weight over it, and this will keep it in place. The construction of the model is now finished.

It is advisable to give the planes a slight camber by the leading edge, but no angle of incidence, as, in the writer's opinion, it is of no use for a model in which no power is exerted.

Fig. 7 shows the finished model.

If the machine has been constructed as shown it should make very good glides, *but on no account should it be thrown, but gently released from the hand with a slight forward motion.* I find it best to launch the models from a window of my house which overlooks a field; then I can get quite long and steady glides. After a few experiments with this type, the beginner will soon be able to make tractor biplanes, Taube or other monoplanes, or Dunne biplanes, using the same method of construction, but in the case of the biplanes substituting struts instead of the under bracings or "load wires" as described. Working on these lines I have made many different types up to about 1 ft. in span, and on one of my tractor biplanes I fitted a small carved propeller with some success. It certainly added considerably to the model from an appearance point of view.

Lastly, a few hints on flying these particular models.

1. Don't throw away a model because it won't fly the first time. Try different weights and positions of same, and tune it up.
2. Rather have too much *head* weight than too little. In the latter case the machine will be unstable; in the former it will fly fast if the elevators are adjusted.
3. Camber only serves to stabilize the machine. Contrary to theory, it does not increase the lift on these machines (they have no power), but rather tends to decrease it.
4. Don't expect your model to "loop the loop." It will not do so unless thrown against a high wind. That is not gliding.
5. Don't fit useless accessories; they simply hamper the machine's progress. A chassis is all right, but there is really no need for wheels.—*Courtesy "Flight."*

Model Clubs Attention

A letter has been received from Mr. W. H. Logue, Jr., 931 North Broadway, Baltimore, Md., in which he requests that we notify the secretaries of the various model clubs to send him information concerning models and the holding of contests.

We need not emphasize the opportunity that is afforded to the clubs to co-operate for the good of the game, and we ask all model flyers collectively or individually whose desire it is to help broaden the field of model aeronautics to send Mr. Logue all information, descriptions, photographs, etc., that they have in their possession concerning model aeroplanes and the holding of contests. In conclusion we would state there is no time like the present.

Boy Scouts Active with Models

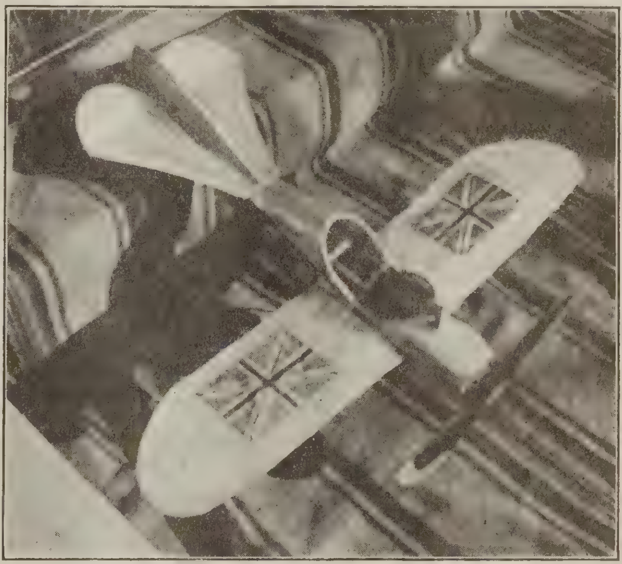
Indianapolis, Ind.—Model aeroplane contests in which model aeraplones made by Boy Scouts were tested for distance and duration of flight were held at the state fair ground April 6th in connection withe the celebration of Scout Week in Indianapolis.

A Model Warplane

The model shown in the accompanying photograph was constructed by Master R. O'Neill, of Montreal, Canada. The machine was designed after one of the leading warplanes now in active service abroad and in carrying out the entire features he did not fail to include the identification marks which are of utmost importance in the war zone.

The dimensions of the model are as follows: Length of fusilage, 23 inches; span of top wing, 33 inches; span of lower wing, 29 inches, both having a chord of 7 inches. Motive power is derived from two ⅛-inch square elastic strands which operate a multiple gear to which is attached a ten-inch propeller.

In coloring the model a dull aluminum was selected. Complete the model weighs 12 ounces. Perhaps the most interesting feature of the model is the ability to change it to a monoplane by the removal of the upper wing after which the lower wing is raised to the sockets in the fusilage which were especially arranged for that particular purpose.



Model warplane.

The Broadway Model Aero Club, Baltimore, Md.

A meeting of young men interested in the sport of model aeroplane flying was held in this city on Tuesday, April 10, at the office of Mr. William H. Logue, Jr., 931 North Broadway. At this meeting a permanent organization, which will be known as "The Broadway Model Aero Club of Baltimore, Maryland," was formed. This club will, from this time forward, hold regular meetings at which scientific construction and flight articles by authorities in this matter, etc., will be discussed intelligently and interestingly.

At the last meeting the officers were elected. Also an article by one of the leading authorities in the United States, concerning the construction of these models, was read by the secretary of the club.

Model planes are now being constructed by all of the members of the Broadway Aero Club. Exhibition flights will be arranged and contests will be held at an early date in one of the public parks.

The Broadway Model Aero Club now consists of ten members, all of whom are very enthusiastic regarding the outcome which they are certain will "bring Baltimore into the limelight." A campaign is now under full sway to increase the membership of the club. This campaign is being conducted by the membership committee, Masters Black, Borgfeldt and DeLauder. Any young man of good character and interested in aeronautics is eligible for membership. Apply to the secretary, C. Howard Black, 927 North Broadway, who will refer the matter to the membership committee at the following meeting.

Officers: President, Charles J. Koch; Vice President, Justice F. Mueller; Second Vice President, Robert E. Borgfeldt; Secretary, C. Howard Black; Treasurer, Thomas DeLauder.

Membership Committee: C. Howard Black, Robert E. Borgfeldt, Thomas A. DeLauder.

Contests Committee: Charles J. Koch, Justus F. Mueller, Ernest Schneider.

Director: Mr. William H. Logue, Jr.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested

The New Slang

Every industry or sport must have its own little slang words and phrases. Just as in baseball the runner "Purloins the second hassock," instead of merely "Proceeding to second base before the spheroid can be propelled thither by one of his opponents," in football the giant full-back "hits the line for ten yards."

All this slang we are acquainted with, but never before did we know that the science of aviation had a little slang all, all its own. However, we were seated at our desk one day last week, when the door opened and a man walked in. We walked up to him and asked him what he wished. And then he started! As near as our troubled brain can remember the words, we reproduce them:

"Say feller, push on the foot-bar,—yer comin' to a turn: let out your gas, kid,—yer miles off'n the ground. Don't give me no oil, because I'm the best mechanic dat ever lived. Why, I'm the guy dat took the *buck* out of turnbuckle, and if dat ain't so, you can cut me loose from me parachute and let me drop:—der ye get dat?"

"But, my dear sir!" we exclaimed.

"Lay off dat 'Dear sir' stuff" he returned. "T'row in yer gyroscope, kid; yer wobbling all over the place! Bank yer turns, kid, yer skiddin', yer skiddin'! I came in here ter get a job, and I wants one,—see? If I ain't the goods I says I am, loosen me guy-wires and let me fall apart. I'm the original twin-six kid, and I know it! S'long!"

And he went out into the stillness of the night.

War Nates

Jess Willard has been accepted to drive a speed-scout after he takes his pilot's license. Aviation schools are busy reinforcing all machines.

No Zeppelin parties have been given by der Kaiser for quite some time. The English are quite worried over his lack of neighborliness.

When interviewed by our Russian correspondent, the former Czar intimated that he didn't care a whoop who won the war.

Six aeroplanes passed over Main Street, Hickville Center, last week, and an enterprising pickpocket got six watches in the excitement.

It is reported that a number of young men are organizing little flying parties in search of submarines, off the Atlantic coast. When submarines are seen, the young men plan to give them pleasant little surprises in the form of steel bombs. No doubt the submarine people will appreciate the harmless joke.

A great argument took place recently at the Oshkosh Aviation School about the correct way to loop-the-loop. One of the men described the sensation so vividly that eight men became dizzy and had to go outside for air.

Quite a Mechanic

Ethel: Yes, Charlie is a very good mechanic. Why, its wonderful how he can overhaul a motor! Just the other day he took his motor apart, and when he put it together again he had enough parts left over to make a motorcycle engine!

Our Own Dictionary

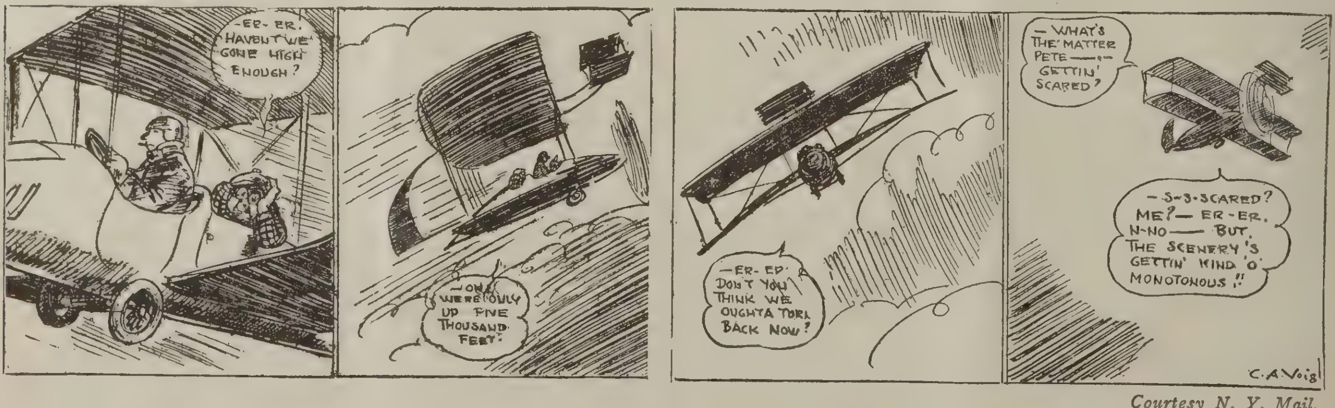
Spasm 3.

Brace—To ask for money.
Muffler—Worn by aviator in winter flying.
Strut Socket—A knee joint. (Very deep.)
Wing Stagger—Seen on Ornithopters.
Revolution Indicator—An uprising.
Water Jacket—Raincoat.
Shock Absorber—(Ask O'Sullivan—*he* knows.)

The Dying Aviator

Tune: "The Dying Lancer."

A handsome young airman lay dying,
(Chorus): *Lay dying,*
And as on the aer'drome he lay,
He lay,
To the mechanics who came round him sighing,
Came sighing,
These last dying words he did say:
He did say:
"Take the cylinder out of my kidneys,"
His kidneys,
"The connecting rod out of my brain,"
His brain,
"The cam box from under my backbone,"
His backbone,
"And assemble the engine again."
Again.



-ER-ER. HAVEN'T WE GONE HIGH ENOUGH?
-OH! WE'RE ONLY UP FIVE THOUSAND FEET!
-ER-ER DON'T YOU THINK WE OUGHTA TURN BACK NOW?
-WHAT'S THE MATTER PETE—GETTIN' SCARED?
-S-S-SCARED? ME?—ER-ER. N-NO—BUT, THE SCENERY'S GETTIN' KIND 'O' MONOTONOUS!!

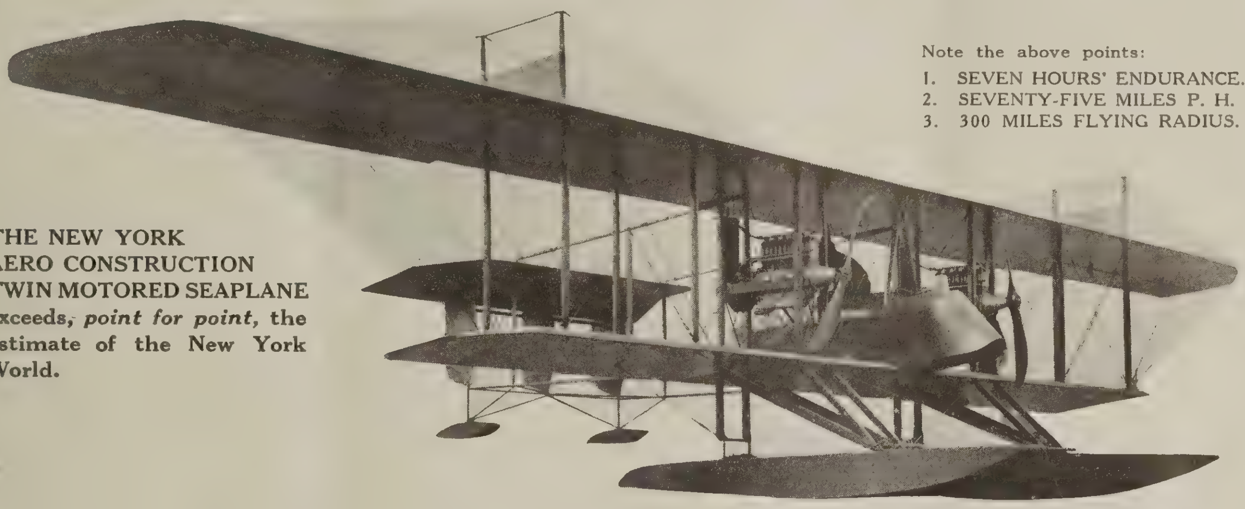
Urgent Need for Air Scouts

(Editorial in The New York World)

"Assuming seven hours' endurance, the air scout, at say seventy-five miles an hour, will be enabled to proceed out three hours, and return in three hours, leaving one hour for a safety margin. He ought to be able to locate an enemy fleet, or a convoy of transports, at a distance of 300 miles from the base from which he started."



Note the above points:

1. SEVEN HOURS' ENDURANCE.
2. SEVENTY-FIVE MILES P. H.
3. 300 MILES FLYING RADIUS.

THE NEW YORK AERO CONSTRUCTION TWIN MOTORED SEAPLANE exceeds, *point for point,* the estimate of the New York World.

PERFORMANCE

The New York Aero Construction Company's Twin Motored Seaplane has a maximum speed of 85 miles per hour, excelling the estimate by ten miles per hour. Yet it has a slow landing speed of 43 miles per hour, allowing the landings to be made within a much smaller space than is ordinarily the case. But what is even more important in coast defense work is the fact that it has a

FLYING RADIUS OF NINE HOURS

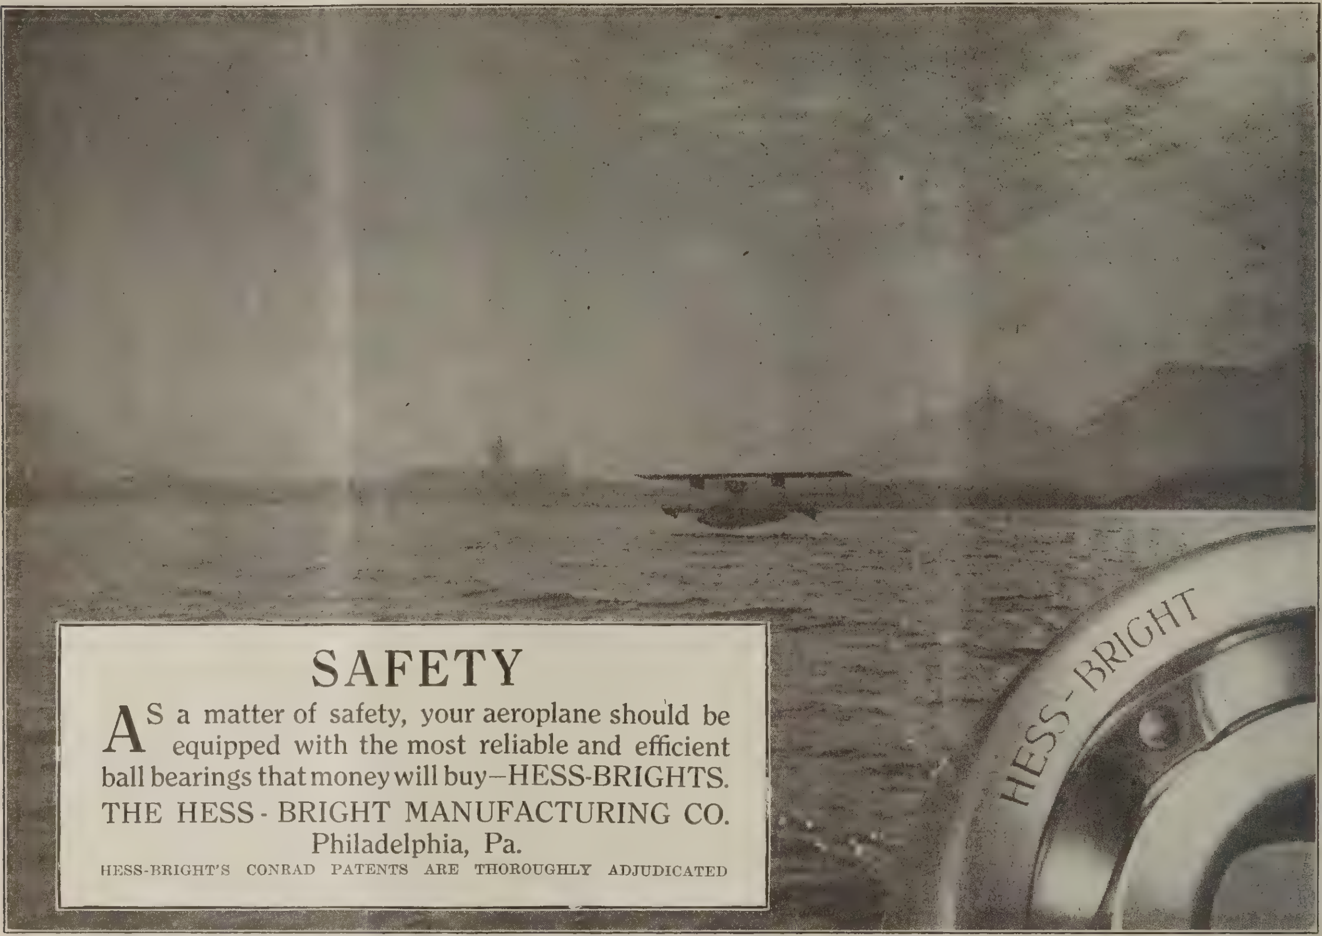
The advantages of a high speed and a wide flying range are obvious. The coasts of the United States are long, and the swifter the machines that guard them, and the longer they can stay in the air, so much better and more easily are the coasts patrolled. The seaplane mentioned in the editorial of the World, could, flying at full speed for its seven hours' flying radius, cover 515 miles. The seaplane of the New York Aero Construction Company could cover 680 miles.

820 Sq. Ft. Supporting Surface.
Two 100 H.P. Aeromarine Motors.
Weight 2,700 lbs. Useful load 1,700 lbs.

Maximum speed, 85 Miles per hour.
Minimum speed, 43 Miles per hour.
Flying radius, nine hours.

Designed and constructed throughout under the supervision of Mr. Warren S. Eaton.

NEW YORK AERO CONSTRUCTION COMPANY. Factory, Newark, New Jersey



SAFETY

AS a matter of safety, your aeroplane should be equipped with the most reliable and efficient ball bearings that money will buy—HESS-BRIGHTS.

corrected for instrumental errors by adding or subtracting the correction found by calibration tests over the cameras or speed course. This number is then again corrected for height by dividing by the square root of the density. The result should give the true air speed, subject, of course, to errors of observation. The numbers so obtained are plotted against the "standard" heights, *i. e.*, the average height in feet corresponding to the density during the test. A smooth curve is then drawn through the points and the air speeds at standard heights of 3,000, 6,500, 10,000, 13,000 and 16,500 read off the curve. These heights are chosen because they correspond closely with 1, 2, 3, etc., kilometres. The indicated engine revolutions are also plotted against the standard heights, because these observations form a check on the reliability of the results; also the ratio of speed to engine revolutions at different heights may give valuable information with regard to the propeller.

Table VI gives complete results of one of our tests of air speed at heights. The table refers to the same machine as Table V, which gives the results of calibration tests of the air speed indicator. Fig. 5 shows the smooth curve drawn from the calculated data, the actual air speeds calculated from the observations being shown by crosses, while the observed engine revolutions at the same heights are marked in by dots. Fig. 6 gives another example, where the observations were very good; the air speeds and r.p.m. lie very closely on a smooth curve except at one point (about 10,000 ft.), where they were probably affected by a downward current of air.

In a brief paper it is impossible to do more than explain the more important of the "performance" tests of aeroplanes, considered solely as flying machines. For military purposes a number of tests are necessary, some of which cannot easily be reduced to figures. Nor can it be supposed for an instant that the methods outlined here are final; aeroplane testing, like all other work connected with aeroplanes, is only in its infancy; and as time goes on, and knowledge accumulates, better methods and instruments will be evolved. There are some who lay considerable emphasis on the necessity of every test instrument being self-recording, and although this scheme appears at first sight Utopian and would relieve the pilot of a single-seater of considerable trouble, there are many objections to it when considered in detail, not the least of which is the difficulty of getting new and elaborate instruments made at a time when all manufacturers are fully engaged on other important work. When an observer can be taken I would personally place much more reliance on direct observations at the present time, and one great advantage of direct observation is that the results are *there*, and no time is lost through the failure of a recording instrument to record, a circumstance which is not unknown in practice. So far as we use recording instruments we use them only as a check on direct observations, although we shall probably soon adopt recording air speed indicators for the calibration tests. But whether recording or direct reading instruments are used, it is, as I said before, the flyer on whom the accuracy of the tests depends. I feel that too great stress cannot be laid on this; he is the man who does most of the experiments, and like all experimenters in every branch of science, he requires training and a great deal of practice. Although the methods themselves may be greatly changed, this much may perhaps be claimed, that the general principles on which they are founded are sound, and will only be altered in detail. The importance of the work can hardly be exaggerated; model experiments are notoriously subject to scale and other corrections, which if not carefully scrutinized may be very misleading, and it is only by accurate full scale work that we can hope to maintain a steady improvement in the efficiency of aeroplanes.

DISCUSSION

Captain Sharren, R.A.F., stated that in the main the same methods are employed by the R.A.F.

He used to think that a statoscope was unnecessary in speed tests as it was possible to fly level by aneroid, as he had found by experience that it was possible for a good pilot to fly for ten minutes at a time without the aneroid showing any change. He had, however, come to the conclusion that this might be due to lag in the aneroid.

They used a bubble statoscope now of a similar pattern but rather smaller, and therefore lighter, than that shown by the lecturer.

They also used the climb meter shown, but he was surprised to hear it called the "Raf" or "Navy" type, as he had never heard either expression before. At the R.A.F. it was usually known as the "copiometer," because it was copied from an adaptation of thermos flask, which he believed originated in Germany, where it had been used for some time in balloon ascents. It was not altogether reliable owing to the effect of acceleration on the column of liquid.

He considered it essential that men taught to carry out experimental flying should be selected from men who were accustomed to experimenting in other branches of science.

Captain Grinstead thought that it would be found necessary in the future to measure other qualities of the aeroplane than merely the air speed and rate of climb, to which tests were limited at present. He suggested that instruments would be required to measure the time it took an aeroplane to come on to a bank and the time taken to turn through a given number of degrees.

Major Filon considered that absolute accuracy was most important, and that this could only be obtained by standardizing methods in order that a true comparison of results could be obtained.

He thought that the results obtained should be circulated among manufacturers and designers, as a very small difference in the performance of two machines might lead to important developments in design, which emphasized the necessity for accuracy.

He enquired if the lecturer had experienced any difficulty owing to the lag in thermometers, as he had found that in some cases this was considerable. He considered it important that temperature should be measured directly instead of relying upon so-called "laws" which were unreliable and unsatisfactory.

He did not entirely agree with the lecturer in neglecting recording instruments, as these were undoubtedly capable of great improvement, and he thought it was expecting too much from a pilot that, in addition to flying the machine, he should have to read an aneroid, air-speed indicator, thermometer and revolution indicator.

Squadron Commander Busteed expressed the opinion that the work could be got through quicker without any instruments at all. A machine had to be got out as soon as suitable weather occurred, but if instruments were employed it was usually found that something was adrift and the opportunity was lost.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

THREE MEDALS OF MERIT were awarded by the Aero Club of America for the following notable records:

J. FLOYD SMITH, who created three new World hydro altitude records in a Martin seaplane: January 12, 1916, with one passenger, 12,333 feet; January 11, 1916, two passengers, 9,524 feet; February 16, three passengers, 9,608 feet.

C. C. CULVER, Captain, U. S. A., for his great achievements in developing wireless equipment for sending and receiving messages from aeroplanes. All his experiments and achievements were made using a Martin Military Tractor Biplane.

A. D. SMITH, Corporal, U. S. A., who created a new hydro duration record February 19, 1916, in a Martin seaplane by remaining in the air 8 hours and 42 minutes.

Many other performances of note prove the certainty and efficiency of our designing and the superior construction of our aircraft.

WRIGHT-MARTIN AIRCRAFT CORPORATION

60 Broadway -:- New York

(*Continued from page* 195)

requirements and in a communication which we received the end of June, they stated that they had placed an order for six machines of that kind, and as soon as they had decided on the type of landing chassis which they wanted, they would have the changes made to conform with the other six machines. By October they had not yet settled on the type of landing chassis to be adopted.

"But at the time of the flight, we had occasion to talk to a prominent engineer, who had just returned from Europe, where he had seen all the European machines, and reported that the Curtiss twin-motored battleplane was a more efficient flyer in every way than the best European twin-motored machines. This battleplane, equipped with two motors of from 160 to 200 H. P. can, we believe, equal any performance of European machines of the same type. Half a dozen other manufacturers, including well established firms such as the Aeromarine Plane and Motor Company, the Burgess Company, the Gallaudet Aircraft Corporation, the Sturtevant Company, the Thomas-Morse Company, and other firms, have received orders from the Army and the Navy, and are now about to produce twin-motored hydroaeroplanes. With the experience they are gaining, we can expect that they will soon turn out efficient aeroplanes. This is also true of newer concerns, such as the New York Aero Construction Co., the A. S. Heinrich Corporation, the General Aeroplane Company, and others. So we may say that we have good prospects of getting twin-motored machines comparable with the best European machines of the same type. Of course, we must order and use machines, as perfection can only be obtained through evolution by actual use.

"(4) *The fast single passenger fighting machine:* The first demand for this machine in the United States came only a few months ago. Of late the Army and the Navy have both been planning to place orders for machines of this type, and half a dozen of the manufacturers have stated that they are ready to turn them out. The thing to be decided just now is whether the Army and Navy are willing to adopt the foreign specifications, and content themselves with fighting machines that have a factor of safety of two or three and carry two hours fuel and land at a speed of close to 85 miles an hour. If they will content themselves with this, we feel certain that American manufacturers can turn out fighting aeroplanes that will make a speed of close to 140 miles an hour, the best actual performances obtaining abroad with machines of good flying qualities and fast climbing speeds.

"But this low factor of safety and extreme landing speed, while necessary when it actually comes to fighting enemy aviators, can be dispensed with, at the cost of only about five to ten miles per hour speed, so long as our aviators do not have to fight enemy aviators, and thereby save considerable breakage of men and machines. Our committee came to the conclusion after watching the succession of breakages of the fast British fighting machines which has been tested at Governor's Island during the past few weeks. This machine was so lightly constructed and landed at such great speed, that there was breakage at practically every landing. Finally the two British officers who brought it over crated it away. The account of the death of Norman Prince, of the Lafayette Corps, tells that the machine he was flying landed at a speed of close to 100 miles an hour. The new Spad is almost as bad in so far as the factor of safety and landing speed are concerned. They are machines to use in battle, and American aviators will use them when they get there, but it would be wrong to say that they are better than the American fighting machines being turned out."

In rendering this report to the Commander of the Third Naval District, and in subsequent making it public, the Committee on Aeronautics has done a constructive patriotic service, and their findings will do much to dispel the feeling that has been caused by the misrepresentative statements of ill-informed persons who have unthinkingly, and not realizing they might hurt the aeronautic industry, have stated that our types did not compare favorably with European machines.

American constructors are ready and able to construct machines in large quantities as good, if not better, than any being constructed in Europe, and all that it is necessary to do to prove this is to have the authorities place orders which will call for continued, steady deliveries, for the next three years, so that our constructors will produce the good machine needed to train and equip the thousands of aviators whom we should send to co-operate with our allies in Europe, and thereby render the utmost service in helping win the war.

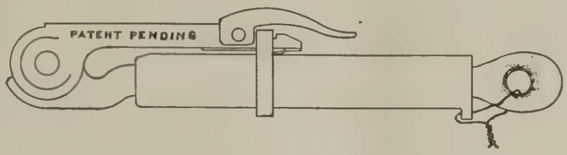
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

Aeronautic Maps

THE Aeronautic Library has secured the exclusive agency from the Sperry Gyroscope Company for the sale of the Sperry Aeronautic Maps and is now ready to deliver maps New York-Chicago; New York-Newport News; Long Island and vicinity, etc.

Every aviator appreciates the value of an accurate map when making cross-country flights, and the Sperry Aeronautic Maps, and Sperry Map Holder, supply this necessity.

The map can be turned easily in the holder bringing constantly before the aviator a chart of the locality above which he is flying.

The equipment is light in weight and can be fixed to instrument board without interference with the other instruments.

Prices and details on application.

INSURANCE

In aeronautics, quality ought to be paramount—price a secondary consideration.

That is why HESS-BRIGHT BALL BEARINGS are coming into their own in this field, as they have in most other lines of industry.

They are the highest grade bearing that can be used in the Airplane.

Their cost is justified.

The safety of the aviator should come first and because the dependability of the motor rests in a measure upon its bearings, no bearing can be too good.

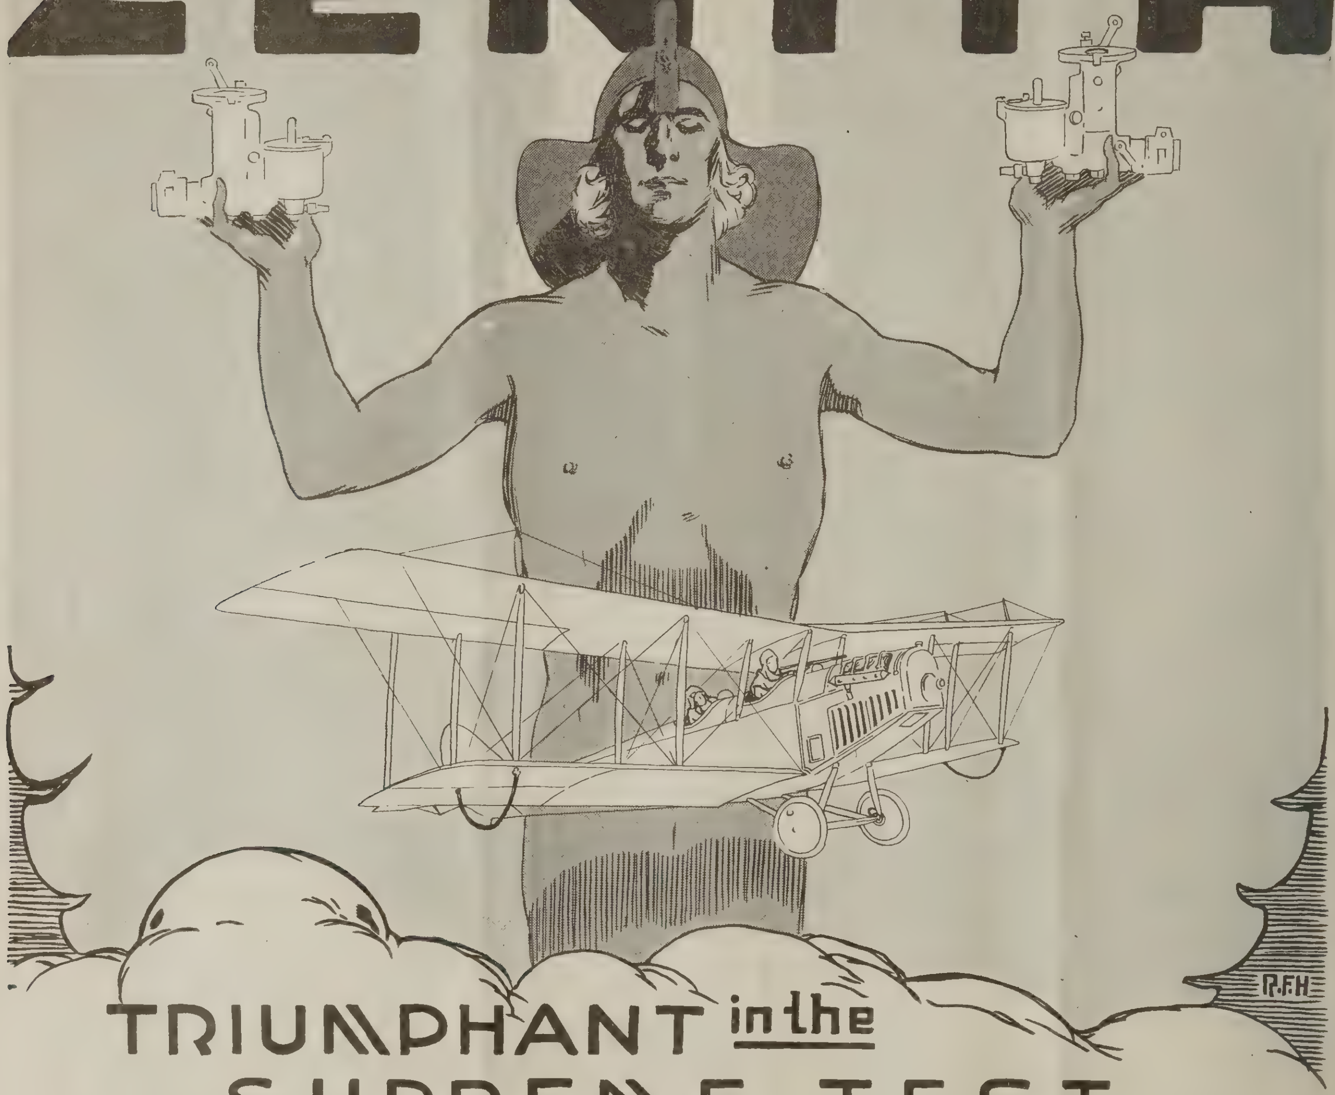
ZENITH



TRIUMPHANT in the SUPREME TEST

Soaring among the clouds, thousands of feet above the earth, the air-man cannot adjust a carburetor in trouble. With life hanging in the balance, he must have dependable carburetion at all times and under all conditions.

The airplane is the carburetor's Supreme Test for reliability and endurance. Experience has proven that there is one carburetor which meets these requirements with uniform faithfulness — the simple, trouble-proof, plain tube ZENITH.

The United States Army and Navy use the ZENITH, as far as the records show, on practically 100% of their flying machines in service and on order. All quantity builders of airplane motors in America use ZENITH on their product. Over 98% of all recognized aero-motors built in this country in the past two years are ZENITH equipped. These facts tell the story.

For the manufacturer and owner of touring car or commercial vehicle this same reliability and endurance is available. The ZENITH gives the maximum of satisfaction always — a satisfaction many thousands of users are enjoying today.

SELECTIVE DRAFT SYSTEM ADOPTED IN BOTH HOUSES BY OVERWHELMING VOTE

APRIL 28th will go down in American history as the day when the most helpful step towards insuring the peace and welfare of the Republic was taken. The selective draft system was adopted by both Houses by overwhelming vote. While the details have not been settled, the principle has been adopted. Senator Chamberlain and Congressman Kahn, the two men who did so much to put through the large appropriation for aeronautics last year were the sponsors for these important measures.

The Aero Club of America and *Flying* and *Aerial Age* played an important part in bringing this about, not only through their efforts which began three years ago, but through their very recent energetic efforts, the details of which have not been published, which resulted in hundreds of thousands of signatures being sent to Congress demanding the adoption of Universal Training.

SENDING 5000 AMERICAN AVIATORS TO FRANCE PROPOSED IN CONGRESS AND IS FAVORED BY BRITISH AND FRENCH AUTHORITIES

THE plan to send 5000 American aviators to France, as America's first step towards participating with the Alleis in the fight for Civilization and Humanity has met with general enthusiasm.

The plan received its approval simultaneously in Great Britain, France and United States. General Joffre himself asked for American aviators in his very first request.

In Congress the project was brought up by Congressman Murray Hulbert and in the Senate it was discussed by Senator Wadsworth.

"America Should Lose no Time in Getting Aeroplanes Under Way and Men Under Training," Say Allied Aeronautic Authorities

BRITISH HEADQUARTERS IN FRANCE, April 28, (via London.)—Wholly informal but decidedly interesting conversations between British and French flying corps officers as regards the possibility of early American participation in this fascinating phase of the war have been going on behind the lines here. It is generally agreed that apart from naval activity the flying service offers the quickest opportunity for effective military help from America against the common foe, and the expectation is that just as the aviation branch of the service proved so attractive to the young men of both England and France the youth of America will be drawn toward it.

Already plans are making to increase the number of Americans now flying for France, while all the members of the British Royal Flying Corps are ready to welcome and aid in the training of Americans in all the arts of war flying. It is realized that the United States Army is not on a war basis regarding machines, but it is understood that both the British and French services are prepared to furnish them temporarily, just as these two services now exchange machines as necessity demands.

America, of course, is expected to throw her organizing and manufacturing ability into supplying their own machines to her fliers, but the modern aeroplane with its tremendous power housed in a very compact, very light engine, with delicate instruments, unerring balance, and sensitive controls, is an extremely complicated affair and its construction is a matter of months.

Just now the single-seat fighting scout is the machine of the hour. Such machines must stand the terrific strain of fighting tactics—rolling, looping, nose-diving, side-stepping. It is no unusual thing nowadays to see a pilot seemingly fall out of control 2,000 feet or more, and then flattening out and sailing serenely away. The strain of this manoeuvre is tremendous.

The Associated Press correspondent has talked with many British flying officers of distinction and all agreed that the only way to train men for war flying is in actual fighting. They frankly say that in this way many men may be lost, but that those who survive are worth their weight in gold and prove brilliant flight and squadron leaders.

Officers of the British flying corps say that America must be prepared to pay such a price; that she must remember this when the losses begin to mount up. She must understand, they point out, that out of these losses will come men who will reflect glory upon her colors and lend brilliance to the brighter pages of her history.

It is, of course, possible to train men far from the battle field. They may become proficient in every trick of flying known to the science in this training. Their real service, however, only begins after they have proved themselves "over the line." The British have developed brilliant fliers at their training grounds in England, men who have mastered every technical point of aviation leaders. But each one of them upon reaching France must be attached to a squadron as an ordinary fighter and win his way upward through the soul-seaching shock of actual battle. Some of these men succumb, but the survivors more than repay the cost.

America, it is said, can render a great service to the Allies by sending over pilots at the earliest possible moment. They can join the British corps at once, and as they prove themselves can be reclaimed by America for organizing and training her squadron as these become available.

The care and maintenance of aeroplanes requires the constant attention of skilled men. If America would render an immediate service, according to the view here, she might send over 5,000 fitters, riggers, and mechanicians to take up this branch of the service now and learn every phase of the work of grooming and handling the delicate machines.

The air service does not stand still. Almost each day brings changes. It is the feeling here that America should lose no time in getting machines under way and men in training. The Allies hold the hard-fought mastery of the air, but they must be in a position always absolutely to overwhelm the enemy and keep him on the ground. The youth of America and Britain, it is thought behind the lines here, should, with their common ideals, common language, common love of sport, and common courage, skill, and daring, find ideal companionship in this hazardous but romantic war in the air.

Gustave Hervé Appeals for Aviators

Paris, April 26—Gustave Hervé makes an appeal in his paper *La Victoire* to the United States to send an army to France at the earliest moment possible. He says he is sure an ingenious people like the Americans will be able to raise and equip an army of 100,000 men within three months, as well as sending enough aeroplanes to prevent Germany keeping a single aeroplane or observation balloon in the air and to keep the heavy Krupp artillery blind by the Allied supremacy of the air.

CONGRESS ASKED TO ADOPT PLAN TO SEND 5,000 AVIATORS TO FIGHT WITH ALLIES

IN a stirring address delivered on the floor of the House of Representatives, Congressman Murray Hulbert proposed the sending of 5,000 aviators to fight with the Allies, and told how they can be had and trained. Following is his address, quoted from the Congressional Record for April 27:

Our honored guest, Right Hon. Alfred J. Balfour, some time ago stated on the floor of the House of Commons:

"The time is here when the command of the sea will be of no value to Great Britain without corresponding command of the air."

A great military figure, the late Lord Kitchener, stated that a well-trained and equipped aviator was worth a whole army corps.

And Marshall Joffre idolized upon his arrival in the Capitol City last Wednesday with no less enthusiasm than he was received at the gates of Paris upon his return from the Marne, after he had stemmed and turned the tide against the destruction of civilization, declared on the deck of the Mayflower as he passed historic Fortress Monroe:

"The French idea of an American participation calls for a fighting force supported by auxiliary services and a strong aviation section."

American Aviators In France's Great Work

We hear expressions of opinion daily that the present war will be decided in the air, and we know that the recent allied victories have been due to the fact that the allies have proven themselves to be the masters in aerial navigation; yet every cable dispatch of aerial accomplishment fills us with a thrill of pride because some valiant and brave American has been a participant. Only a handful they have been, but they have proven the statement that an aviator is worth a whole army corps. Today we are to decide what our first contribution to the common cause is to be. We are to select the most powerful, the most effective weapon with which to strengthen the hands of our Allies. It is conceded that it will require from nine months to a year to train and put a substantial American force in the field, but there is no doubt whatever that we could train and equip and send to Europe 5,000 aviators within a much less period; moreover, while many of you have expressed your doubt with reference to securing a sufficient number of volunteer soldiers, and others question the propriety of invoking the selective draft, it is a conceded fact that there are thousands of young men waiting to enlist in the air service, inspired by the novelty and fascination of aerial activity, so that we have no fear of the success of the volunteer service and no need of conscription so far as the air service is concerned. They are men of the best type, men like those brave and daring American aviators, William Thaw, Norman Prince, Elliot Cowdin, J. R. McConnell, C. C. Johnson, Lawrence Rumsey, R. Luffberry, Kiffin Rockwell, Bert Hall, Didier Masson and other members of the Lafayette Corps, who fought side by side with the French and British aviators for the past two years; **therefore I want to urge this House today to go on record in favor of a plan to make our first contribution to the common cause 5,000 well trained and equipped aviators.**

Our allies appreciate the fact that we can best help them by sending aviators, and they have already suggested, in fact, that it be done.

The prominent naval strategist, Rear Admiral Bradley A. Fiske, in a recent communication to the Board of Governors of the Aero Club of America, as the representative aeronautic body in this country, suggested that the club point out the advisability of sending to Europe a large unit of aeroplanes with well trained aviators and appropriate armament; and in response to an inquiry cabled by the French and British newspapers to the Aero Club of America, Mr. Alan R. Hawley, its president, replied:

"We have thousands of applications for aviation training from college men who are anxious to join the Army and Navy reserve or would like to join the American aero squadron in France or the Royal Air Service. Large aviation camps could and will undoubtedly be established immediately where students will be given their preliminary training in aviation and in military matters in general. The Aero Club has received a large number of offers of extensive tracts of land to be used free of charge as aviation training camps, and it has also received liberal offers of funds from patriotic citizens for training aviators in large numbers. But I believe that to give the best results and avoid confusion the training of 5,000 aviators to be sent to Europe should be undertaken by the United States Government. The suggestion comes at the most opportune moment, and you may rest well assured that there will be no lack of co-operation in the United States to make the plan effective. In the light of the situation here one is safe in predicting that of all of the forces to be dispatched from this side to the European battlefield the strong probability is that amongst the first will be a large number of representative aerial squadrons, consisting of the very best material that America can furnish, all fired by patriotic enthusiasm at the prospect of flying under the 'Stars and Stripes.'

A year ago, when Villa's raid brought out the fact that we had only 12 aviators and 6 aeroplanes available in the Army air service to meet the emergency, an appeal was made for aviators and aeroplanes by the Aero Club of America, which very patriotically undertook to train and equip aviators for the national defense and build up this very important branch of the Army and Navy.

Thousands Want to Join Air Service

The response to the Aero Club's appeal was amazing. Applications came from all over the country by telegraph, mail, telephone, and personal calls of the applicants. The energetic officials of the Club, who, by the way, have been the patriotic, far-seeing men who started and supported with all their might and to the fullest extent of their means the movement to build up our national defenses, arranged for the training of over 100 aviators, some of whom have actually become Army aviators, and others are to be found in the Aerial Reserve Corps, the Naval Reserve Flying Corps and in the aviation sections of the militia throughout the country.

But the response to the appeal brought such a flood of applications that it became imperatively necessary for the Government to take up and deal with it promptly and substantially. I had the pleasure of being a member of the committee which called on President Wilson on June 29, 1916, to bring to his attention the fact that there were 2,000 patriotic young men who had been waiting patiently—and impatiently—for a chance to enlist in the air service. When you consider that at that time one of our greatest national problems was, as it still is to a great extent, the problem of getting men to enlist in the Army and Navy, you realize why the Aero Club of America, of which I am proud to be a member, realized the importance of bringing the matter to the attention of the President of the United States, who, realizing its importance, immediately authorized the creation of the Aerial Reserve Corps, as provided for in the national defense act of June 3, 1916.

The Aerial Reserve Corps, which is part of the Officers' Reserve Corps, was authorized on July 13, 1916, and a few days later when, with the committee of the Aero Club of America, I called on Secretary Baker and at the offices of the aviation section of the Signal Corps, we were advised that the plan of the department was to immediately select 297 men to be trained as officers and aviators in the Aerial Reserve Corps, and to send them to some 10 private aviation schools, which were in a position to arrange for their training. Unfortunately this plan was not accomplished through the summer and fall, and the winter conditions were considered too difficult for student aviators to face, so the establishing of aviation training camps and the training of hundreds of aviators for the Aerial Reserve Corps was postponed.

Lack of Facilities Prevents Training of Aviators

Several aviation training schools are being established by the Army and the Navy, and while the plans are being made, I want to emphasize a condition existing which, if taken advantage of, will cause the thousands of aviators whom we should have as soon as possible, not only for national defense but also to send to Europe as our first contribution to help our allies to wage this fight for humanity and civilization. I know of many Members of Congress who have received applications from young men desirous of joining the Aerial Reserve Corps, the Naval Reserve Flying Corps, and who on applying to the War and Navy Departments have received the same answer that I have received, and thousands of young men have received, to the effect that the Army and the Navy are not in a position to take care of these thousands of patriotic young men who want to give their service for the upbuilding of our aerial service. The departments advise that the aviation schools are filled to the limit of their capacity, which is roughly estimated at less than 300 aviators, being trained, including the Navy Aviation School at Pensacola, the Army schools at San Diego, Cal.; Mineola, N. Y.; Memphis, Tenn., and the two new temporary aviation schools established at Chicago, Ill., and Essington, Pa., and the private schools being conducted for the Army at Miami, Fla. and Newport News, Va.

20,000 Applicants for Air Service

I am advised that the War and Navy Departments and their recruiting offices have been flooded with applications from men who want to join the air service, and that to put the estimates of those who have applied for training in the past few months at 20,000 would be conservative. The Aero Club of America alone has received about 4,000 applications in the past three months, including hundreds of applications from college men, some of whom have already been partially trained at private expense.

Patriotic Volunteers Doing Pioneer Work In Aerial Preparedness

In some cases young men, after waiting for months for action, undertake to pay for their own training, and there are today about 200 young men learning to fly to prepare themselves at private expense to be ready for the Army, Navy, or Reserve air service. A group of patriotic men, headed by Mr. H. P. Davison and Mr. Lewis S. Thompson, and with the co-operation of Messrs. Alan R. Hawley, Rear Admiral Robert E. Peary, John Hays Hammond, Jr., and Henry Woodhouse, are establishing a school to train 100 young men in aviation. Last year they founded Aerial Coast Patrol Unit No. 1, which gained distinction in the Mosquito Fleet maneuvers last September, and has been doing pioneer work in naval aeronautics. When war with Germany appeared to be inevitable, these young men left Yale University, where they were studying, and 29 of them reported to the aviation school in Florida, where they have been undergoing intensive training in aviation. They will now return to New York in a few weeks, and 100 will train at one single large aviation school. Two other groups of 12 patriotic men have formed Aerial Coast Patrol Units Nos. 2 and 3, and are taking aviation training at their own expense. Recently some Columbia University men formed Aerial Coast Patrol Unit No. 4, and within a few days they had 200 applications from Columbia men, and they are now making efforts to raise sufficient funds to purchase aeroplanes for training.

On March 10 an official of the Aero Club of America, Mr. Henry Woodhouse, delivered two addresses—one to Princeton University men and one to the alumni of Georgia Institute of Technology, and recommended that they form aerial coast patrol units. Today, thanks to patriotic men who presented the aeroplanes, a unit is training at Princeton. The suggestion to form an aero unit at the Georgia Tech. resulted in some 350 Georgia Tech. men applying for training. The officials of the college presented the names of these men to the Chief Signal Officer several weeks ago and told him that the Georgia Tech. will be glad to give the grounds to establish an aviation school and to also establish a course in the theory and application of aeronautics in the institute. Another patriotic man, a member of the Aero Club of America, last summer established an aviation training camp at Governor's Island and paid tens of thousands of dollars for preparing men for the Aerial Reserve Corps.

Aviators Trained by Private Contributions Is All There Is for Aerial Defense of Third Naval District

Those men and the men trained at Mineola, also at the expense of citizens fired by patriotic impulse, are now all that we have for the aerial defense of the Third Naval District. Still another member of the Aero Club of America, Mr. W. Earl Dodge, has been supporting an aviation training camp for training men for the Aerial Reserve Corps and has spent over $100,000 to help the upbuilding of our defenses.

Mr. Emerson McMillin, another veteran worker for national preparedness connected with the Aero Club of America, gave $34,000 towards the training of those aviators who are now available for the aerial defenses of the Third Naval District. And a few days ago a group of patriotic ladies formed the Aerial Aid Society for the purpose of paying for the training of 12 men and forming a unit of the Aerial Coast Patrol. The ladies of the National Special Aid Society have also contributed from time to time during the past two years towards the training of aviators. In fact, there was contributed the sum of $59,000 to train, equip, and support the First Aero Company of the New York National Guard before the War Department contributed a cent toward their upkeep. I know this was also true in Massachusetts. Mr. T. Jefferson Collidge, of that State, contributed close to $10,000 for training militia aviators in Massachusetts and New York. Amounts were also raised in Rhode Island, California, Michigan, New Jersey and other States.

I could go on quoting case after case of demonstrations of practical patriotism, including offers of seaplanes and seaplane stations for use by the Army and the Navy, by Rodman Wanamaker, J. P. Knapp, August Belmont, Mrs. William H. Bliss, Mr. Floyd-Jones and others; and I also could give the names of those patriotic young men like F. Trubee Davison, Robert A. Lovett, G. G. Depew, Frank Goodyear, David Clinton Backus, J. F. Knapp, Charles B. Wrightsman, Duncan Forbes and others, who are not only paying for their own training but are also organizing units of the Aerial Coast Patrol.

It is not necessary for me to point out that the country at large appreciates the necessity of upbuilding our aerial defenses and the national demands that steps be taken immediately to train and equip at least 5,000 aviators. The action of the Sixty-fourth Congress in voting appropriations amounting to about $18,000,000 for the Army and the Navy for aeronautics proved that the country had just begun to appreciate the need of developing our aerial service.

I dare say that if a canvas were taken it would be found that the country demands that prompt action be taken in building up an air service equal to the air service of the first-class European countries.

Air Service is the Balance of Power

The air service today is the balance of power which decided the daily victories of the armies in the present war. Several weeks ago, before the present drives of the Allies started, there took place a succession of aerial engagements which lastd for several days, until the Allies were victors. Having mastered the enemy in the sky, it was easy to drive them from their intrenchments. Having supremacy in the air, the Allies could prevent the German aviators from following the movements of the Allies, whereas the Allied aviators had free access over the German lines.

Aircraft Needed to Protect Billions of Dollars' Worth of Shipping

We are going to ship billions of dollars' worth of supplies to the Allies, and we shall have to protect every dollar's worth of those supplies and every ship employed in transporting them from the attacks of submarines and from submerged mines. Nothing else is so well adapted for protecting our harbors and shipping lanes from submarines and mines as the seaplane, dirigibles and observation balloons, a fact which has been amply demonstrated in the present war. Great Britain has 107 aeronautic stations along her coasts. And yet the coasts of Great Britain total only about 1,500 miles. With thousands of miles of coast we should have at least as many stations as Great Britain has, extending from Maine to the State of Washington. The National Aerial Coast Patrol Commission, of which I have the honor to be one of the commissioners, has been pointing to this vital need for the past two years and urging action.

On April 13 I presented to this House the plan for the aerial defenses needed for the Third Naval District, a basic plan of aerial defenses suitable for the 13 continental and two insular naval districts, prepared by the Advisory Committee on Aeronautics which is co-operating with the commandant of the Third Naval District in the organization of the Naval Reserve Forces. This plan shows what must be done to establish an aerial coast patrol substantial enough to protect our shipping. I pointed out in that report that Sir Edward Carson, on February 21, 1917, reported to the British Government that since the commencement of the war the British Navy, with the co-operation of its most efficient aerial coast patrol, had examined 25,874 ships. During the first 18 days of February 6,076 ships arrived in ports of the United Kingdom, and 5,873 ships had cleared the ports convoyed by dirigibles or seaplanes. Sir Edward Carson is authority for the statement that from the beginning of the war up to October 30, 1916, the British Navy transported across the sea 8,000,000 troops, 9,420,000 tons of explosives and material, 47,504,000 gallons of gasoline, over a million of sick and wounded, and over a million mules and horses and so forth. It cost Great Britain approximately $350,000,000 to build her present air service, half of which was spent for the naval air service and aerial coast patrol.

What would the fate of the Allies have been if Great Britain had hesitated in investing large sums in a substantial air service?

And, now that the United States is about to undertake to ship billions of dollars' worth of supplies, we need a substantial air service and aerial coast patrol to protect our ships from U-boats and mines.

Our neighbor, Canada, sent 600 aviators to England since the beginning of the war, and is now spending $80,000,000 in aeronautics and in training and equipping 20 aero squadrons. The Allies know the valor and daring of the American aviators. **So the Allies hope for that kind of assistance and co-operation; they need thousands of them, and we should not lose time in trainng and equipping and sending them.**

Department of Aeronautics Needed to Relieve Overburdened Signal Corps and Bureau of Operations

To train these thousands of aviators to be sent to Europe and the thousands more needed for her national defense, to protect the billions of dollars' worth of shipping, will take an

(*Continued on page* 271)

THE NEWS OF THE WEEK

W. Earl Dodge Presents Hangars to Third Naval District

Mr. W. Earl Dodge, the New York millionaire, who has been conducting, at his own expense, an aviation camp for college men at Newport, R. I., and at Jacksonville, and recently offered his $200,000 yacht to the Government, has made another valuable contribution toward the upbuilding of the aerial defenses of the Third Naval District. He has offered to build three steel construction aeroplane hangars at any of the naval aviation stations Rear-Admiral Nathaniel R. Usher, the Commandant of the Third Naval District, may decide. The offer was made through Mr. Alan R. Hawley, the chairman of the Advisory Committee on Aeronautics co-operating with Admiral Usher in the organization of the Naval Reserve Forces, and Admiral Usher promptly accepted it, and the hangars will be set up at one of the seaplane stations being established on lands offered free of charge for use by the Aerial Coast Patrol and the Naval Militia Aviation Section.

Mr. Dodge's aviation school at Jacksonville, which is in charge of Mr. F. C. G. Eden, will soon graduate ten students, all college men, who will then apply for admission in the Aerial Reserves. Their training and maintenance have been paid for entirely by Mr. Dodge.

The Dodge school is to be moved to Long Island within a few weeks.

University of Illinois Wants Aviation School

Champaign, Ill.—President Edmund J. James, Mayor Swigert of Champaign and Mayor Browder of Urbana, have joined in a request to Major General Thomas H. Barry of Chicago, that he establish a navigation school near the University of Illinois. The county fair grounds, which cover fifty-five acres, are offered as a site. The university also offers the use of its armory, other buildings and the parade ground.

Work Being Rushed on Aeroplane Factory

New Orleans, La.—New Orleans will be placed on the map as a manufacturer of aeroplanes by the Richardson Aeroplane Corporation, Incorporated, which has started the construction of its factory on Orleans Canal and Lake Pontchartrain. The company is a local enterprise and is rushing its plant to completion in order to tender its output to the federal government and other governments of the entente allies which are begging for flying machines. It will be the first aeroplane factory in the South and is expected to attract great attention to this city.

St. Louis Opens Campaign for U. S. Aviation School

St. Louis, Mo.—Contributions are being received for a campaign inaugurated by the Missouri Aeronautical Society and other organizations interested in aviation for the purpose of raising a fund to lease grounds in the St. Louis district which are to be placed at the disposal of the United States army for an aviation field.

John G. Lonsdale, treasurer of the society, is receiving contributions, which range from $5 to $1,000. The men interested in bringing one of the aviation stations to St. Louis, are anxious to collect sufficient money to wire the department an offer of a site.

Albert Bond Lambert has sent a telegram to the War Department, in which he offered the department free the use of six licensed and experienced balloon pilots as instructors and the use of balloons and grounds. The labor and gas also will be supplied free, Lambert wired.

Deficiency Bill Carries Appropriation of $54,450,000 for Aviation

The Deficiency Bill under consideration by the House of Representatives at date of writing carries an appropriation of $54,450,000 for aeronautics.

Lieut. Vernon Castle Here

Lieutenant Vernon Castle of the Royal Flying Corps returned to this city last week after ten months' service on the British front, during which time he brought down two German flyers. He was discovered by Frank Tinney, the comedian of "The Century Girl," who, while poking fun at the director of the orchestra, suddenly saw Mr. and Mrs. Castle seated well in the front of the theater. Tinney had been discussing the airs he wanted the orchestra to play when he said: "Let us have some air appropriate for our distinguished visitor, Vernon Castle."

Mr. Castle could not say how long his furlough was to be, and refused to discuss details of his service with the Royal Flying Corps. He arrived in Canada on April 23, according to a report from Toronto, with other officers to assist in the training of new Canadian airmen.

Later the spot light man at the opening of the new "Midnight Frolic" on the New Amsterdam Roof singled out Mr. and Mrs. Castle from the throng of dancers, and the audience applauded, led by Ethel Barrymore.

Stalnaker to Form Aero Squadron

W. E. Stalnaker, vice-president and director of sales of the Pathfinder Company, has tendered his services to Harry B. Smith, adjutant-general, in recruiting an aero squadron of 168 officers and men. "I am already in touch with some high quality men throughout a number of states," wrote Mr. Stalnaker, "most of whom are members of the Society of Automobile Engineers, or the American Automobile Association, or both, and will make the very best material for an organization of this kind. I am ready to commence recruiting immediately on notification of your acceptance."

General Smith in his reply thanked Mr. Stalnaker for the offer and said: "At the present time we have no authority to organize an aero company, but request has been made of the department and we hope to be advised regarding it in a very few days. I will communicate with you just as soon as any definite information is received."

New Aeroplane Dope

The perfection of a liquid chemical composition or aeroplane "dope" which will make not only the wings, but the entire wood construction of an aeroplane absolutely fire-proof, thereby eliminating one of the greatest dangers in aviation, is announced in a letter written to the Board of Governors of the Aero Club of America by Mr. W. R. Weeks, president of Weeks & Company, of 95 Liberty Street, New York.

This solves a problem in war and peace. In war it means that incendiary bullets will fail to set an aeroplane on fire, as they do now, which means death to the aviator and observer, because the fire usually burns vital parts before the pilot can land the aeroplane. It also means the elimination of fires from different causes.

It is almost impossible to keep the various parts of the plane adjacent to the motor and propeller free from gasoline, and machine oil makes the danger of a disastrous blaze from the back-fire of the engine a constant menace.

Mr. Weeks in his letter to the Board of Governors of the Aero Club states:

"Oil and gasoline, spilled or splashed over the plane surfaces, when ignited by back-fire, will not burn the fabric if it has been treated with our dope—the fire cannot reach the fabric and will not spread beyond the extent of the oil-covered area. This will be a wonderful protection to the machine when on the ground, and will also be a decided element of protection against fire when the machine is flying even if hit by shrapnel fire.

"Should the gasoline tank explode in the air and blazing gasoline run out over the rudder, our dope would absolutely protect the rudder and control from burning, thus enabling the aviator to volplane to a landing.

"In addition to the dope for aeroplane fabric-covered surfaces, we have simultaneously perfected a real fire-proof paint for the protection of the wooden parts of aeroplanes. This paint in case of fire acts exactly like the metal covering on wooden doors. Intense heat may carbonize the wood but our fire-proof paint will keep the support intact.

"The utility of this invention is vital to present aeroplane construction where the element of eliminating all possible weight is so important. Heretofore it has been found necessary to use metal for the base and supports of the engine, and steel in various parts of the construction, to insure a degree of safety against destruction by fire where the nearby parts become oil-soaked.

"It can readily be seen that considerable weight can be saved here if wood can be so fire-proofed that it can be substituted for metal in many parts of the frame. We shall take pleasure in demonstrating the effectiveness of our fire-proof paint at the time the official test is held."

The officials of the club are very much impressed by this invention, the details of which will be considered at the meeting of the Board of Governors.

Hangars and one of the Curtiss machines of the Princeton Aviation Corps. Lieut. E. R. Kenneson is head instructor

Lanzius Aircraft Company

With the manufacturing facilities of three large up-to-date factories in New York, Tennessee and New Jersey, the Lanzius Aircraft Company, of New York, is now in a position to execute orders for the Lanzius changeable angle of incidence aeroplane, in any type, for land or sea, or for standard and special design aircraft, either wood or steel construction. The company furnishes with its standard equipment, Duesenberg motors, recognized as one of the most powerful and efficient aeronautical motors on the market.

Possibility of Aviation School in Kentucky

Lexington, Ky.—A short time ago two young men of this city requested the Lexington *Herald* to find out what possibilities there were for receiving training in aviation. The editors wired the Aero Club of America, and received the following response:

"We beg to reply to your telegram of the 11th. Flying schools are not too plentiful at this time and there are many applicants. Perhaps as near to you as any are the Benoist School at Sandusky, O., and the Williams School at Celina, O. The Curtiss Schools, which have high standings, are probably pretty well filled up with applicants.

"For a more complete list of schools we suggest that you write to FLYING Magazine, 280 Madison Avenue. They should have the latest information.

"If it were possible for you or your friends to interest a few patriotic people to buy a couple of planes from some manufacturer you could organize a unit of, say, twelve men to learn flying and probably the manufacturer would gladly arrange for flying instruction.

"If your friends simply wish to enter Government service and get flying training there under enlistment, we suggest application to Chief Signal Officer, U. S. A., Washington, D. C., for Army Reserve or to Bureau of Navigation, Navy Department, Washington, D. C., for Naval Flying Reserve.

"If we can give you further information or assistance please call upon us. Yours very truly,

AERO CLUB OF AMERICA."

The *Herald* has now opened a fund to which citizens of Lexington may subscribe to purchase one or more aeroplanes.

Bridgeport Aviators Called to Service

Bridgeport, Conn.—Activities which have prevailed at the state armory since the first call was issued to the local soldier boys, extended to the aviation corps when it received its official call from the war department for immediate mobilization. This order affects twenty-five men, for the most part new recruits, who have enlisted within the past few weeks. The men were ordered to report at the armory by Lieutenant A. C. Chippendale who has been in command since the departure of the naval militia.

Exactly where the corps is ordered to report cannot be published, except that the men will be sent to training quarters somewhere in the east. Some of the men have not yet received their equipment, but will be obliged to leave in civilian attire if it does not arrive before the hour of departure.

U. of P. Show for Aeroplane Funds

Pittsburgh, Pa.—Successes in the four large cities of the east, where they have given performances, presage for the Mask and Wig Club, scheduled to give a performance in the Schenley Theater, when a two-act musical comedy, "Mr. Rip Van Winkle," will be presented, a crowded audience of Penn alumni and their friends. The net proceeds of the display will be devoted toward the purchase of aeroplanes, field pieces and rifles for the several battalions of the University of Pennsylvania now in training under a Regular Army officer.

Retired Officers Recalled

The drain upon the officer-personnel of the Army caused by the war preparations now being made is strikingly illustrated by the recall to active service of Col. William A. Glassford, U. S. A., ten days after his retirement was ordered. Colonel Glassford has been detailed as departmental aeronautical officer of the Western Department. The Signal Corps Aviation School at San Diego, Cal., of which Colonel Glassford was head when he was retired on April 11, is at present under the command of Col. Alexander L. Dade, Cav., U. S. A.

New Searchlight Tested

Tests of a new and very powerful type of searchlight, designed for use in conjunction with anti-aircraft defenses, were made at the Mineola, N. Y., aviation field recently. Preliminary reports contain the statement that watchers were able to "pick up" an aeroplane two miles away and follow it without trouble. One of the searchlights in use was of 1,000,000 candle-power, with a lens sixty inches in diameter.

Prominent British Aviator Discusses Aeronautics

Maj. L. W. B. Rees, the aviator who accompanies the British war commission, thinks it entirely probable that after the war aeroplanes will cross the ocean and be used in a commercial way. The British airman has been in many battles in the air and has watched the development of the aeroplane in the war. The English machines, in his opinion, are a trifle superior to those of the other nations, though France, he said, is running neck and neck with the British. Maj. Rees would not comment upon American machines.

"It is marvelous what wonderful development has been made in the aeroplane since the war began," said Maj. Rees, at the Shoreham. "In the two years and eight months that the struggle has lasted the speed maximum of aeroplanes has increased almost beyond belief. A year ago it had attained 118 miles an hour; today it is in the neighborhood of 125, and I am told since coming to America that a new Vickers machine in this country has been built to make 137 miles. Really, it's hard to believe, isn't it?

"Yes, I think it quite probable that aeroplanes will be crossing the ocean after the war, when they will be put to other work than war. In this country, I believe, you had a machine all ready for crossing, and I have no doubt it would have been successful. Just recently a French aviator in the ordinary army type of machine made a sustained flight of more than seven hours. It is only a question of the number of tanks to be carried."

Maj. Rees is retiring and modest. He walks with a limp, the result of a bullet in the knee received in an air battle for which he won the Victoria Cross. The major would not recite the story of that fight, but said merely that it didn't worry him much. Maj. Rees paid Immelman, the German aviator, who was killed more than a year ago, a high compliment, saying that the Britishers had a great regard for him because he played the game fairly.

Pennsylvania Aero Club Studies Navigation

Philadelphia, Pa.—To best serve the country and aid in bringing about a successful culmination of the war, many members of the Aero Club of Pennsylvania will study navigation. A class was formed after Henry A. Wise Wood, vice-president of the Aero Club of America, told them that the science would be of great practical benefit to them if they joined the aviation service and that those unsuccessful in entering that branch of the service would find it invaluable if they joined the navy. Many other members of the club will accept positions in aviation schools and aeroplane factories to get a practical working knowledge of aeronautics.

The navigation school will meet twice a week in the office of Joseph A. Steinmetz, president of the club, in the Morris Building. The school will be conducted at the expense of President Steinmetz.

An expert navigator will be engaged to teach the scholars the rudiments of navigation. In twenty lessons, it is thought, those who attend will get a fair theoretical knowledge of the science which can be best supplemented by enlisting in the aviation corps or in the navy.

"By learning navigation," Vice-President Wise Wood said, "you will be doing something of great practical benefit to the country."

New Wisconsin Test Room

The Wisconsin Motor Manufacturing Company has recently added a new test room which is entirely electrically equipped.

Each test stand has an individual electric motor generator unit. When an engine is completed in the assembly department, it is sent to the test room and connected up with the motor generator which acts as a motor and drives the engine until it is sufficiently free to allow it to be run under its own power. A uniform product is assured as each instrument board is equipped with meters which give the actual power required to drive the engine.

When the engines are sufficiently free they are started and run under their own power, driving the motor generator as a generator. The load is then gradually increased until motor develops the required power and then it run under full load for several hours.

The engine is then picked up with an electric crane, of the monorail type, and taken to the final inspecting department, where the motor is completely dis-assembled and all moving parts are given a thorough inspection and adjustment, after which motor is again placed on the test stand and run again for several hours. It is then ready to be shipped.

The large number of special motors built, made it necessary to have a test stand which can easily be adjusted to any width of supporting arms and to any drop or rise. The motors are connected to the generator with an ingeniously designed coupling, which is readily assembled in a few minutes.

All the current that is generated by the generators during tests is reverted into the factory line and used to drive the machinery, giving the benefit of power which otherwise would have been wasted.

Each motor has an individual exhaust pipe leading to the outside of the building. These pipes are underground. A connection is arranged at each test stand for water, gas and gasoline. The motors are run on illuminating gas unless a fuel economy test or carburetor test is desired.

A new experimental laboratory has just been completed. This is equipped with a thrre hundred horsepower Sprague dynamometer so arraigned that a motor can be mounted on either end and driven in either direction. Complete equipment has been added for making horsepower and torque curves, fuel economy curves, oil consumption curves, friction horsepower curves, etc.

This laboratory will be used for experimental work in connection with the improvements of the product.

Japanese Owners of the Standard Aero Corporation Sued by John E. Sloane

The Japanese owners of the Standard Aero Corporation, of which Harry Bowers Mingle is president, have been sued by Mr. John E. Sloane. The details of the suit are given in the New York *Times* for May 1st, as follows:

"A suit of John Eyre Sloane, an inventor of aeroplanes, who married Miss Madeleine Edison, daughter of Thomas A. Edison, against the Mitsui Company, a Japanese commission firm, for an injunction and an accounting, was revealed in the Supreme Court yesterday, when Konosuke Seko of 150 West Seventy-ninth Street, general manager of the Mitsui Company, was examined in Sloane's behalf.

"Sloane also names as defendants the Sloane Manufacturing Company and Shunzo Takaki, assistant manager of the Mitsui Company. The Sloane company is a New Jersey corporation which manufactures airplanes at Plainfield, and has 50,000 shares of stock valued at $10 each. Sloane held 26,500 shares of the stock. He alleges that he agreed to borrow $30,000 from the Mitsui Company through Takaki to finance the manufacture of airplanes for the Russian Government, giving his stock as security, and that it was agreed his shares were to be returned as soon as the loan from the Mitsui Company had been repaid from the profits. Without his authority, and in violation of the agreement, he also alleges, Takaki in May, 1916, transferred his stock to the Standard Aero Corporation in which the defendants are interested.

"Sloane charges that after his majority stock in the company had been transferred the defendants "stripped the Sloane Manufacturing Company of its assets and highly profitable business," and the Standard Aero Company took over the business. He wants the defendants enjoined from carrying out their purposes and demands that they account.

"Seko, manager of the Mitsui Company, examined by Milton Mayer for the plaintiff, testified that his company had some dealings with Thomas A. Edison, as the result of which the loan to Mr. Edison's son-in-law was made. Sloane found himself unable to get the financial aid he expected from his relatives, Seko said, and finally adjusted the matter by turning over the stock in payment."

Rapid Work at Princeton

The Aviation Corps recently founded at Princeton University is a model after which other colleges well may follow.

Under the leadership of Mr. James Barnes of the class of 1884, funds amounting to $200,000 were collected from Princeton Alumni, and the Corps was incorporated. The activity that followed is worthy of commendation, both for its efficiency and its speed.

On Saturday, the 14th of April, a contract was let out to the Matthews Construction Company of Princeton, New Jersey, for three hangars, to be constructed of wood. Construction was started the next day, and two hangars were ready for the machines the following Friday, the day the first machine arrived. Flying was started two days after the first machine arrived. The Matthews Company built the hangars at cost. Two hundred students have volunteered to take the complete course, which includes radio work, semaphore and wig-wag signaling, telo-photography, and machine gun practise. In addition to the machine already at the field, three others have been ordered, and one is expected this week. Later on the authorities hope to have ten training machines, a twin-motored tractor, and one or two scout machines. All the aeroplanes used are Curtiss JN4B's.

Further funds are needed to carry on the work and Princeton Alumni who are interested may send subscriptions to Mr. James Barnes at the Nassau Club, Princeton, New Jersey.

W. E. Stalnaker, vice-president of the Pathfinder Company, who is organizing an aero squadron

Aviation Field at Westport

Hartford, Conn.—At the April 13th session of the Connecticut Assembly the committee gave approval to the recommendation of the state park commission for $1,500,000 for acquisition of land for state reservations which will include the big aviation field at Westport, and an additional $15,000 for surveys.

Army and Navy Orders

S. O. 93, April 23, War Dept.

Sergt. Clyde B. Hamlin, S. C., 1st Aero Squadron, Columbus, N. M., to San Diego, Cal., for duty at Aviation School.

To be 1st Lieuts., Sig. (Avia. Sec.), O. R. C., from April 2, 1917: Rolph, William T., 21, Oct. 21, 1895, Newport News, Va. Culver, Howard P., Feb. 22, 1893, Newport News, Va.

To be 1st Lieuts., Sig. (Avia. Sec.), O. R. C., from April 4, 1917: Barneby, Walter V., 23, Dec. 6, 1888, Newport News, Va. Kenneson, Edward R., 24, Nov. 4, 1894, Newport News, Va.

Col. William G. Haan, C. A. C., and Capt. Shepler W. FitzGerald, junior military aviator, Signal Corps, are relieved from duty as members of a joint Army and Navy Board for the selection of sites for joint aeronautical stations on the Atlantic coast.

Capt. Follett Bradley, 1st Field Art., O. D., to Fort Slocum, N. Y., with a view to examination for physical qualification for detail to aviation section, Signal Corps.

First Lieut. Seth Low and Cord Meyer, aviation section, Signal Officers' Reserve Corps, to active duty, office of Chief Signal Officer.

Capt. Wiley E. Dawson, retired, at his own request, from duty at the Signal Corps Aviation School, San Diego, Cal., to home. (April 19, War D.)

Signal Corps

Lieut. Col. Edgar Russel, S. C., to be colonel from April 12, 1917, vice Col. William A. Glassford, retired.

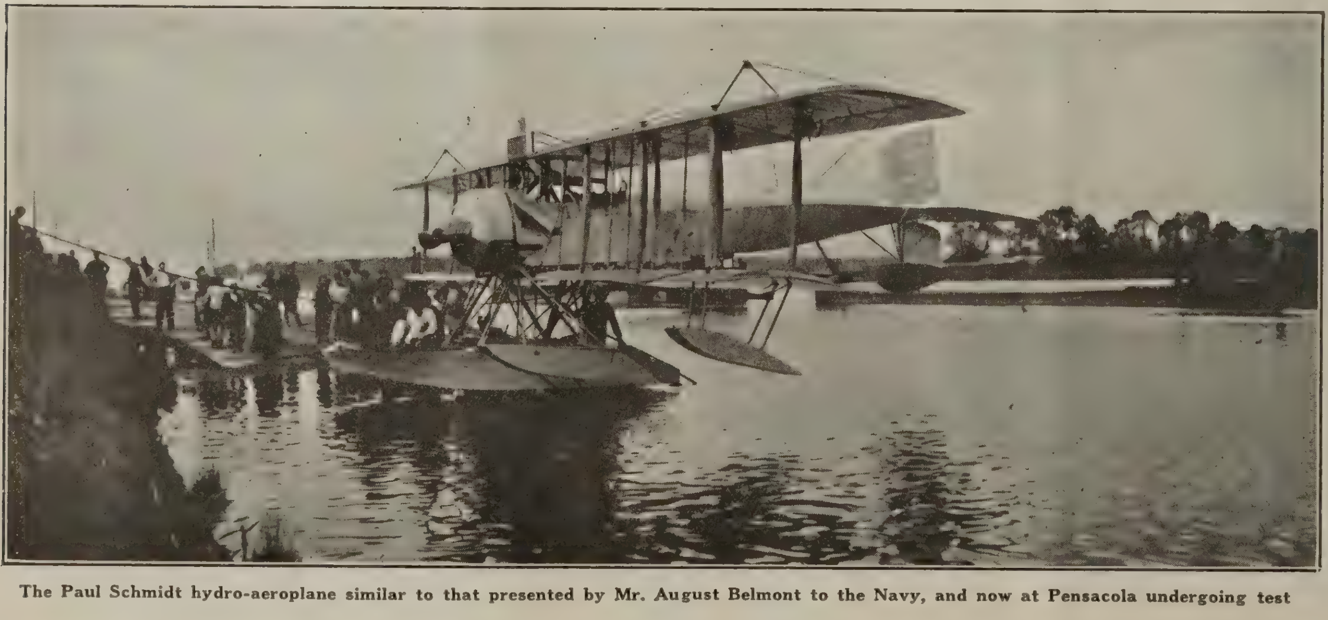
Major Carl F. Hartmann, S. C., to be lieutenant colonel from April 12, 1917, vice Russel, promoted.

Capt. Alfred T. Clifton, S. C., to be major from April 12, 1917, vice Hartmann, promoted.

Capt. Shepler W. FitzGerald, Junior military aviator, S. C., to Gloucester, Mass., about April 23, 1917, for temporary duty at the Hammond Research Laboratory. (April 20, War D.)

The following promotions and appointments in the Aviation Section of the Signal Corps are announced: To be master signal electricians: Sergts. 1st Class Evert L. Moore, John W. Corcoran, John Dolan, Robert Robertson, Calvin T. Stevenson, Arthur B. Neiswander, Leo C. Tobin, William G. Martin, Harry T. Lewis, Charles Payne, Alexander B. Culp, Clarence P. Young, Samuel Katzman, Isaac P. Blade, Walter Brewer, Nemo S. Jolls and George D. Litherland, April 16, 1917. To be sergeants first class: Sergts. Clarence F. Adams, Herbert J. Bertram, Roy S. Showalter, John Pollok, Samuel Hurdus, Clarence H. Maranville, Neil H. Harring, Clyde B. Hamlin, Harry V. Hand, John C. Tureck, Harry E. Weightman, Jacob Anderson, James Murray, John Ross, Henry A. Bergman, Thomas F. Randle, Frank Krick, James MacFadden, Charley B. Ammen, Frank C. Behrend, George W. Kellems, William A. Bechtold, William C. Hunter, Alvah E. Baxter and Charles W. Winters, April 16, 1917. To be sergeants: Corpls. Arthus R. Curphey, Alfred J. Ralph, Oscar Young, David M. Jones, James A. Reardon, Max Miller, Harry Turner, Walter Hannefield, Clarence L. Sanders, George C. Kull, Lawrence G. Wirth, Lawrence M. Gordon, Walter Hitzfeldt, Howard J. France, Lee O. McQuitty, Andrew Anderson, Nick Roeser, Willard W. Warren, Charles O. Watson, Frederick Jansen, Claude E. Fessler, Carl W. Bradbury, Paul A. H. Bellings, Donald Smith, Alexander J. Anderson and William A. Fox, April 16, 1917; Cook Harry F. Gosnear, April 16, 1917, and Pvts. Irwin N. Zuber, March 25, 1917, and Paul J. Corn, April 2, 1917. (April 16, S. O.)

Master Signal Electrician Leon E. Harper, S. C., at Nogales, Ariz., to Manila on transport to leave May 5 for duty. (April 21, War D.)



The Paul Schmidt hydro-aeroplane similar to that presented by Mr. August Belmont to the Navy, and now at Pensacola undergoing test

RUBBER HOSE FOR USE ON AEROPLANES

By PERCY A. HOUSEMAN*

THE enormous increase in the world's output of aeroplanes during the last three years has rendered important a systematic inspection of materials used in their construction.

One of the materials requiring detailed examination is rubber hose, which is held to be the most desirable material for conveying gasoline from the tank to the engine on aeroplanes.

It was found, at the time that a system of inspection for aeroplane materials was initiated in England, that the quality of the rubber being used was quite unsatisfactory. This was probably due in a large measure to the unfamiliarity of the rubber manufacturers with the properties required of gasoline-resistant rubber hose. They appear in some cases to have endeavored to adapt their regular types of material, such as steam- or water-hose, for use with gasoline, with results which were sometimes disastrous to the life of the aeroplane and to its pilot.

The Underwriters' Laboratories of Chicago have published (May, 1914) their requirements for rubber hose to conduct gasoline, and their tests are very thorough. When the hose is to carry gasoline on aeroplanes some modification of the Underwriters' examination seems desirable. Bursting, tensile, and stretch tests on the original hose are described by the Underwriters, and tensile strength is also determined 24 hrs. after gasoline immersion. It may be pointed out that after such a period the rubber recovers, with little deterioration, its original physical properties. It is important to obtain a hose which will show good physical behavior while immersed in gasoline or immediately after removal therefrom. Bursting and tensile tests were given up as specification tests by the writer because, although they furnish helpful information, it was found that they were not adequate to detect tubes which would behave badly towards gasoline when used on aeroplanes.

In drawing up specifications for gasoline-resistant rubber tubing, the following tests were carried out, and found to be suitable for controlling the quality of the tubing.

They are intended to amplify and not to supplant the specifications of the Underwriters' Laboratories.

(1) FLEXIBILITY—The tube is bent to a circle having a diameter (D) which varies according to the inside diameter of the tube (d) as shown below:

d	D
Up to ½ in.	8 times d
9/16 in. to 1 in.	10 times d
1 1/16 in. to 1½ in.	12 times d
Above 1½ in.	14 times d

The diameter of the tube so bent should not change at any point by more than 10 per cent. from its original diameter.

A tube of poor flexibility will show a permanent weak spot if bent sharply a dozen times at the same place.

(2) IMMERSION IN GASOLINE—At first an immersion test of 200 hrs. in cold gasoline of about 0.720 sp. gr. was used. It was found that approximately the same effect can be attained in a shorter time by boiling in gasoline for 1 hr. under a reflux condenser, followed by 24 hrs.' standing in gasoline at room temperature. The approximate increase in weight and volume of the sample (about 3 in. long) is recorded for correlation with the results of the other tests. The decrease in bore at the narrowest part of the tube is also noted and should not exceed 25 per cent., otherwise the supply of gasoline to the engine may be seriously diminished, especially for tubes of less than ½ in. internal diameter.

The adhesion of the rubber to the canvas fabric must remain good, and the "nerve" of the rubber must not be seriously impaired when examined immediately after the gasoline treatment.

This test of strength of adhesion of rubber to canvas, and for retention of "nerve" of the rubber is open to the objection of being too vague, but it was not found expedient to incorporate standardized tests for these properties, and in actual practice no difficulty was ever experienced in judging whether or not a sample passed the test. This test is also a rough guide to the amount of free sulfur present, crystals of sulfur being deposited from a tube containing an excessive amount.

(3) PERMEABILITY TO GASOLINE—A 14 in. length of the tube is held vertically and plugged with a glass stopper at the bottom. A glass tube is fitted to the top, and is filled with gasoline to a head of 12 in. above the top of the rubber tube, and then loosely stoppered. The length of rubber tube exposed to the action of the gasoline is 12 in. At first the gasoline is absorbed comparatively rapidly by the rubber. The level of the gasoline in the glass tube should not be allowed to fall more than 3 in., additions of gasoline from a known volume being made as necessary. The amount of gasoline which permeates through the walls of the rubber tube is noted during the first and second days, as a guide to the behavior of the sample. During the third 24 hrs., by which time the rate of permeation has become approximately constant, the amount of gasoline passing through the tube should not exceed 100 cc. per sq. ft. of original internal surface of the rubber tube.

(4) DRY HEAT—A piece of the tube is heated for 2 hrs. at 132° C. The rubber should remain elastic after this treatment, and should show no signs of stickiness or brittleness, nor should any surface cracks become visible on stretching the sample.

(5) COLD—The tube is immersed in carbon dioxide snow, which was found to render all tubes brittle while they remained cold. The rubber regains its elasticity on attaining room temperature again, and this test was, therefore, discontinued.

(6) BURSTING PRESSURE—Tests on bursting pressures were carried out before and after the permeability test, but were subsequently given up, as it was found that the quality of the tube could be sufficiently safeguarded by the other tests, and, moreover, the pressure to which the tube is subjected in actual service is very slight.

(7) ACETONE EXTRACT, FREE SULFUR, MINERAL SULFIDES, AND SULFUR OF VULCANIZATION are also determined, and furnish useful information in forming a judgment as to the quality of the specimen under examination. The free sulfur should not exceed 1 per cent. of the weight of the finished tube (exclusive of the canvas). Excessive free sulfur will be carried by the gasoline into the cylinders of the engine where it may promote pitting.

(8) ASH—A portion of the rubber is incinerated very slowly, and the amount and composition of the ash determined.

(9) QUALITY OF CANVAS—Tests on the quality and strength of the fabric inserted in the tube were contemplated, but it was found expedient to leave to the judgment of the manufacturer the kind of fabric to be used, relying on the tests already enumerated to control the production of a satisfactory tubing.

When the examination of rubber hose for use with gasoline was commenced, great diversity in construction, composition and behavior was found. Some makers appear to have believed that vulcanized rubber is essentially non-resistant to the action of gasoline, and therefore put as little of it in the tubes as possible. Some tubes yielded as much as 75 per cent. ash, while others gave less than 40 per cent. As great a diversity was found in the composition of the ash. Barium sulphate, lead, zinc, calcium and magnesium were found in a great variety of proportions, each manufacturer carefully guarding his own "mixings" and considering them of vital importance for the production of a satisfactory tube. Some typical figures of ash analyses are appended. The figures for total ash are percentages of the finished tube, excluding the canvas.

TABLE I

TOTAL ASH AND ASH ANALYSES OF GASOLINE-RESISTANT RUBBER HOSE

Description of Tube	Total Ash Per Cent	Percentages of Total Ash				
		$BaSO_4$	PbO	ZnO	CaO	MgO
French No. 1....	51	26	10	..	26	10

British 6-A......	44	..	40	13	2	29
British 7-A......	61	..	60	8	..	3

French No. 1 was not a very good tube. The rubber was somewhat harsh. The tube failed to pass the flexibility test, but was satisfactory for permeability. The adhesion between rubber and canvas at the end of the immersion test was fairly good, but the tube contained as much as 3 per cent. free sulphur. The heat test caused obvious deterioration in the quality of the rubber. Barium sulphate and lime are the chief mineral ingredients.

French No. 2 was inferior to No. 1. The rubber was harsh, and its behavior varied along the length of the consignment, indicating probable uneven vulcanization. Mechanical defects, such as local pitting, were to be seen. The adhesion of rubber to canvas after immersion appeared at first sight to be very good, but this was due rather to the ease with which the rubber itself tore. Lime and magnesia are the most prominent minerals, with barium sulphate as a diluent. Rubber hose for use with gasoline on French aeroplanes is required to contain 45 per cent. mineral matter with a margin of ± 5 per cent., 50 per cent. rubber with the same margin, and to have a density of 1.6 (±0.1).

British 1-A to 1-D, though all from the same make, show wide variations in total ash and in the composition of the ash. The bad feature of both 1-A and 1-B was the weakness of the adhesion between rubber and canvas. Separation of the plies occurred spontaneously under gasoline. The other properties of these tubes were satisfactory. 1-D was a good tube.

British 2-A to 2-E, all made by one firm, show less variation in total ash, but much variation in the composition of the ash. 2-A and 2-B represent respectively outer and inner rubber layers of the same tube. The same applies to 2-C and 2-D. The inner layer of rubber proved to be of better quality for use with gasoline than the outer layer. The adhesion between rubber and canvas was bad. Tubes 2-A and B showed high constriction of the bore. All of these tubes contain a considerable quantity of lead, and 2-E is noticeably high in magnesia.

British 3-A and 3-B—3-A showed bad "adhesion"; 3-B very good adhesion, though the rubber was rather "short" after the immersion test.

British 4-A and 4-B—The product of this firm showed great variability in bore-constriction, but the flexibility, permeability, adhesion after immersion test, and quality of rubber after immersion test were all good.

British 6-A was a good tube. *British 7-A* was too harsh.

A large number of other tubes were examined but most of them showed defects in one or more of the properties tested. Some manufacturers used a certain amount of reclaimed rubber or of rubber substitute, but it is believed that this is not desirable as regards the quality of the product, although it lowers the cost.

One firm made an excellent tube by the use of 45 per cent. Para rubber. The mineral ingredients in this tube were lead, calcium and magnesium. This tube withstood the immersion test with hardly any deterioration in the "nerve" of the rubber, and the adhesion between rubber and canvas was scarcely affected. The bore constriction after immersion test was less than 25 per cent. on a ½-in. tube, and all of the other tests gave good results.

It is probably undesirable to use less than 40 per cent. rubber.

In many cases it was customary to insert a spiral of brass or steel wire in the bore of the tube so as to improve its flexibility. This practice is unnecessary if the walls of the tube are made fairly thick, and in the case of the brass spiral constitutes a possible source for the entry of copper into the rubber.

It was found that a decided improvement in some of the properties of gasoline-resistant rubber hose could be achieved by changing the manner in which the canvas was inserted. The usual method was to friction the canvas with a very thin layer of the rubber mixing, so that in the finished tube there were virtually three plies, an inner layer of rubber, a middle layer of canvas, usually from 2 to 4 turns according to the size of the tube, and an outer layer of rubber. When a tube made in this manner is subjected to the immersion test the three layers expand at different rates, resulting often in spontaneous separation. The canvas layer expands hardly at all, and so the expansion of the inner layer of rubber is forced inwards, with consequent constriction of the bore. A better method of construction consists in spreading a definite layer of rubber on the canvas, so that in the finished tube the thickness of rubber between each turn of the canvas is at least twice as thick as the canvas itself. A cross-section of a tube made in this way shows the canvas to be distributed as a spiral through the whole thickness of the wall of the tube. Such a tube shows improved flexibility and better behavior under the immersion test, there being less tendency to separation between rubber and canvas and a smaller constriction of the bore. For tubes up to ⅝-in. internal diameter, two turns of canvas are sufficient. Between 11/16 in. and 1¼ in., three turns are desirable, and for tubes larger than 1¼ in. internal diameter 4 turns of canvas should be used. The larger sizes are used for oil or water.

---

*Formerly Chief Examiner, Aeronautical Inspection Department Laboratories, London, England.

THE 1916 TYPE GERMAN AVIATIK BIPLANE

German pilots affirm that they have climbed with the Aviatik as high as 15,750 feet with their observer and 18.5 gallons of gasoline. The recognized maximum climb is about 11,500 feet with a useful load of 750 pounds.

Tests in France show the following results for speed and climb: Speed at 1,000 metres, 79 m.p.h.; 2,000 metres, 74½ m.p.h.; 3,000 metres, 66 m.p.h. Climb to height of 500 metres, 4½ minutes; 1,000 metres, 9½ minutes; 2,000 metres, 21½ minutes; 3,000 metres, 47½ minutes.

Aviatiks with Benz and Mercedes motors of 220 h.p., differing from the 170 h.p. motor in cylinder bore only, as said to be building. These are to have two machine guns, one of which will fire through the sweep of the propeller, and having a speed of 93 m.p.h. at an altitude of 2,000 metres.

General Dimensions

Wing Span, upper	40′-8″
Wing Span, lower	35′-5″
Chord	6′-1″
Gap	6′-4″
Length over all	25′-4″
Height over all	10′-3″
Weight, empty	1,831 lbs.
Useful load	968 lbs.
Motor, Mercedes	170 h.p.
Speed range (at sea level)	82-49 m.p.h.

Planes

The planes are practically rectangular in shape. Sweepback about 1 degree, 10 minutes. Angle of incidence, 4 degrees, 38 minutes. Dihedral about half a degree.

Wing spread, upper plane, 40′ 8.1″, and lower plane, including the body, 35′ 5″. Chord, 6′ 1″, making the total wing area 430.56 sq. ft., including the surface of the ailerons. Ailerons on upper plane are 7′ 3.6″ long by 2′ 5.1″ wide; surface 17.22 sq. ft. Trailing edge of the aileron rises toward the wing tip, presenting a negative angle at the extreme outer edge.

The wings weigh 308 lbs. Interplane struts weigh 28 lbs.

Fuselage

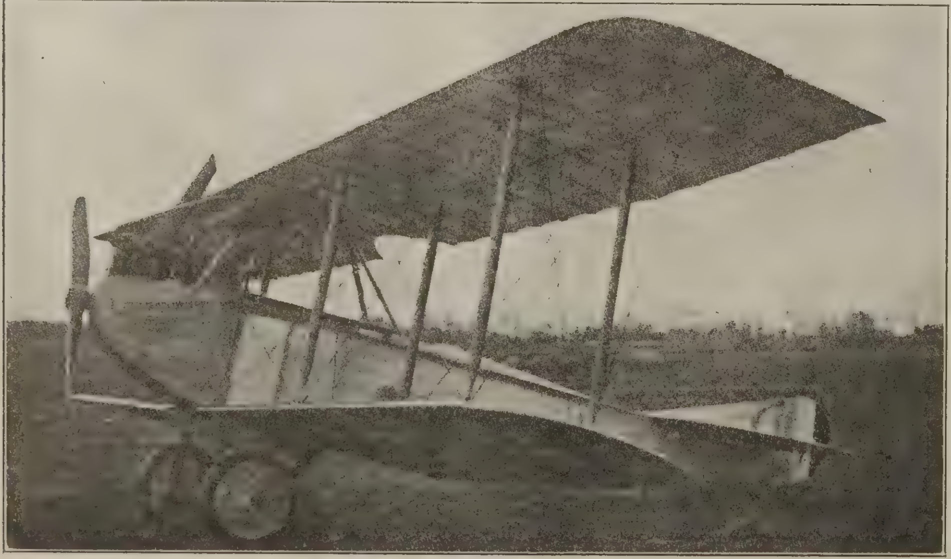
The body is quite similar to the Rumpler and Albatros. It is of box-girder construction with bevelled spruce cross members wired with diagonal stays of piano wire. Fittings are such that the longerons are not pierced.

The cockpit is built of steel tubing. The cockpit frame is of round tubing and the slanting struts supporting the upper plane are of elliptic section.

The body is practically entirely of wood. The four main longerons are of ash, wrapped with fabric from the front of the machine to the back of the rear seat, and from there on of unwrapped pine. Longerons are of constant section throughout their length. The top of the body is covered with arched plates of aluminum.

Steps for access to the cockpit fold inside, and do not project outside the body.

Controls are of the Deperdussin type with aileron cables passing inside the lower planes. The rudder is controlled by a foot bar provided with heel rests of metal.



1916 Aviatik—three-quarter front view.

1916 Aviatik—close view of motor mounting.

Landing Gear

The tread of the landing wheels is 6′ 2.75″. Struts are of elliptic tubing and internally reinforced with wood. The landing gear is held in shape by an oval cross member, horizontal cables and steel cable cross stays. The axle rests inside the points of the two Vs, and is attached to a short tubular horizontal member by means of rubber cord.

The tail skid is of wood, all outside of the body, hanging on a pivot and held in place by rubber rings located inside the body. Underneath it is attached by a metal fitting which encloses the body termination and to which the rear end of the vertical fin is attached.

Tail Group

The stabilizer is fixed and measures 9′ 2.2″ by 4′ 10.2″. Upper fuselage longerons slope downward toward the rear, and the stabilizing plane being placed upon them gives it an angle of incidence of minus 58 minutes to the wings. A projection of the propeller axis passes 5.51 inches below the rear of the stabilizing plane.

Area of the stabilizing plane, including the portion covering the fuselage, is 35.52 sq. ft.

The elevator is in the form of two semi-oval surfaces between which the rudder is pivoted. Over all dimensions of each, 4′ 3″ by 2′ 2″. Elevator area, 12.07 sq. ft.

The rudder is balanced. Height, 3′ 0″, depth 2′ 3.5″; the balanced part adds 10.63″ to the depth. Area, 6.45 sq. ft. including the balanced part which has an area of .81 sq. ft.

The fixed fin is 5′ 1″ long by 2′ 5.5″ high at the rear. Area, 3.23 sq. ft.

Elevator, rudder and fin are built of steel tubing .47″ outside diameter. Edges of stabilizer of .98″ tubing, with ribs of wood. Front edge of elevators of .98″ tubing.

Armament

In front of the pilot, at either side of the body, are two 8.46 inch bomb-launching tubes of sheet metal. The trigger for releasing the bombs is fitted with a spring and the passenger operates it by pulling a cable.

Machine guns are mounted on elliptic tubes curving above and outward from the fuselage. The guns can be fired in nearly any direction rearward and forward except in the direction of the area traversed by the propeller.

Power Equipment

Mercedes motor of 170 h.p. This motor was completely described in the issue of September 11, 1916. Bore and stroke, 140 mm. by 160 mm. Estimated h.p. 170 at about 1,300 r.p.m.

Weight of motor, 673 lbs.; propeller, 42 lbs.; cooling water, 55 lbs.; fuel, 418 lbs. The fuel is calculated for a flight of 4½ hours' duration.

THE MECHANICAL DEVELOPMENT OF AVIATION

By NEIL MacCOULL, M. E.*

AVIATION is one of the most fascinating branches of mechanical engineering. It seem as if it were born in mankind of all ages to long for the mastery of the air,—the mythology of all peoples is filled with evidences of it. Most of us have been raised from childhood on such stories as those of Daedalus and his son Icarus, who attached large birds' wings to their backs by means of wax and flew from Crete to Italy, though Icarus flew too near the sun and the wax melted; or on the story of the winged horses of the Valkyrie in Norse mythology, who flew between the battlefields of mortal man and Valhalla, carrying the bodies of great heroes to their eternal reward in the home of the gods.

The reason for this romantic interest in aviation for the layman is out of my province to explain, but it is easy to put one's finger on the cause of the interest which an engineer takes in this subject. Engineers have always experienced keen delight in tackling and solving difficult problems, and the intensity of the pleasure has increased somewhat as the cube of the difficulties encountered. It was the engineer who by constant patience, and toil, and discouragement and hazard of life, finally wrenched human flight from the fancy of poets and dreamers, and placed it in actual reality in the hands of modern civilization. The great bulk of what is nowadays called engineering offers but few real difficulties; it is merely a matter of producing a mechanism which will run satisfactorily and will be cheap: a matter requiring more common sense than brains, except for the financier who is back of it all. Knowledge of the underlying principles involved such as thermodynamics for example, is not at all essential in many instances, and is frequently not desired.

But the true engineer, the man who, like Alexander the Great, lies awake at night, and worries because of the lack of difficulties obstinate enough to give him an opportunity to try his ability to the utmost, will find aeronautics a field greatly to his liking. In spite of the apparent success of modern aircraft, there is such enormous room for development as to be a great attraction to the man who wants to show results; and the beauty of it is that any man who can improve on what is now being done will show such a vital knowledge of every minute detail of the subject as a whole, and the part he tackles in particular, that he can well be justified in experiencing a thrill of pride when the world examines his work—for we will all know that it was no accident.

It is a matter of historical record that actual experiments were made with artificial wings as far back as the early part of the seventeenth century. From that time on, many experiments were made which gradually led up to gliding flights with rigid wing surfaces such as used in the early experiments of the Wright brothers.

The earliest systematic experiments with mechanical power were started in 1889 by Sir Hiram Maxim. From the data obtained he constructed a very large twin propeller aeroplane in 1893, with steam as the motive power. The span of the wings was 104 feet, which to this day is exceeded only by a very few machines. The great amount of wing surface, and the perfect maze of wires and other parts producing air resistance is very noticeable when compared with modern machines. The total wing area was over 6,000 square feet, which is some twelve times as great as the average military aeroplane—but this was necessitated to a large extent by the fact that it was intended to fly at a speed of only 35 to 45 miles an hour. At such speeds, however, air resistance is not nearly so great as in modern machines which make well over 85 miles an hour. and probably accounts for the lack of any resemblance to the much talked of stream line shapes of today. In the experiments with this machine, the running gear was provided with flanged wheels which ran on a straight level track of 9-foot gage. Strong wooden guide rails of 3 by 9 Georgia pine were constructed along the track in such a way as to prevent the aeroplane from leaving it. Thus, actual flight was prevented, because control and stability were unknown factors and the first data required was only in regard to the ability of the machine to support its own weight. Quite elaborate recording instruments were provided for such quantities as speed and lift. This aeroplane not only lifted its own weight of 8,000 pounds, but also broke the stout plank guide rails which held it to the earth, and caused a wreck. But in spite of being able to support itself it could not be called a successful aeroplane, because its stability and airworthiness were never demonstrated in free flight. In fact, it seems questionable now, that it could have ever been airworthy. The power plant, however, was the one part of this machine which was demonstrated to be successful and is sufficiently interesting to warrant more attention, for I doubt if there has ever been a steam plant of its size which weighed so little as 11 pounds per horsepower, including boiler, engines, condensers, pumps and water supply.

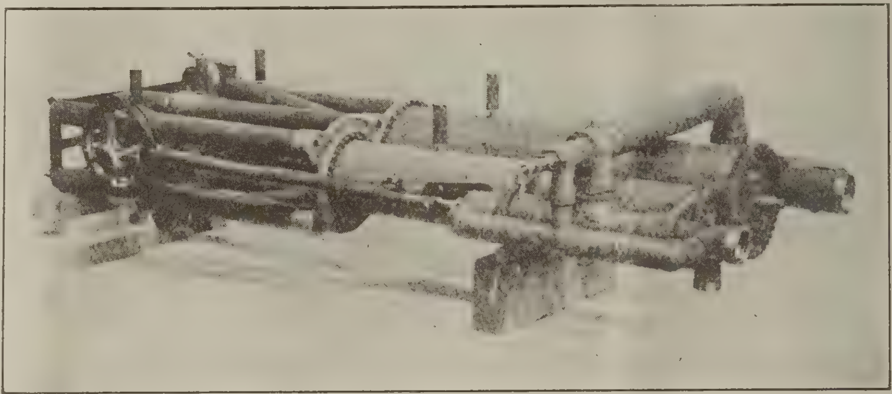

Fig. 2. One of the compound steam engines of Maxim's Aeroplane

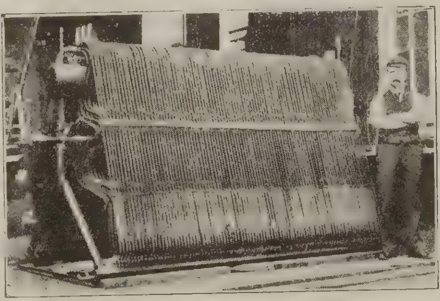

Fig. 3. The oil burning boiler used for both the engines on Maxim's aeroplane

Each of the two propellers, which were 17 feet 10 inches in diameter, was directly connected to a double acting compound engine, with cylinders 5 and 8 inches bore, and a stroke of one foot, high pressure cut-off being at ¾ stroke, and low pressure at ⅝. These engines were constructed almost entirely of high grade cast steel and were very light, weighing but 320 pounds each, complete. With a steam pressure of 320 pounds per square inch, each developed 180 horsepower at 375 r.p.m.,—a weight of only 1¾ pounds per horsepower. A species of safety valve was provided which would discharge into the low pressure cylinder, thus adding considerably to the power when there was an excess of steam.

The boiler which supplied the steam for both these engines was equally a masterpiece. It was constructed of a very large number of ⅜-inch copper tubes 1/50 of an inch thick, and had a heating surface of about 800 square feet, including the feed water heater. It must be realized that tubing such as this was quite a novelty in those days. A strong forced circulation of water was obtained by means of a spring loaded valve in the boiler, which held the feed water at a pressure of 30 pounds per square inch in excess of the boiler pressure. This fall of 30 pounds in pressure acts upon the water in the tubes and forces it down through the large outside tubes shown at the left. Although this boiler with the casing, dome, smokestack and connections weighed less than 1,000 pounds, it supplied all the steam that the engines could possibly use. The weight of the engines and boiler totaled 1,640 pounds, or about 4⅓ pounds per horsepower.

The condensers were made of very thin copper, the individual tubes being shaped somewhat like miniature aeroplane wings in section. By this means they were made to sustain more than their own weight when the aeroplane was traveling at its normal speed.

At almost the same time that Sir Hiram started his experiments, Samuel Pierpont Langley the real "father of aviation," was learning the fundamentals of aerodynamics by means of models with rubber motors. After years of experimentation in which astonishing difficulties were successively encountered and overcome, data was finally accumulated which led to the construction of successful steam driven models. While great difficulty was encountered in developing the aerodynamic properties of the models, even greater difficulty was experienced of a mechanical nature when attempts were made to use steam as a motive power. Mr. Langley acknowledges in his "Memoirs" that he had no professional acquaintance with steam engineering, but that none of the counsel obtained from those possessing more knowledge was useful in meeting the special problems which presented themselves, and which were solved only by constant trial and error.

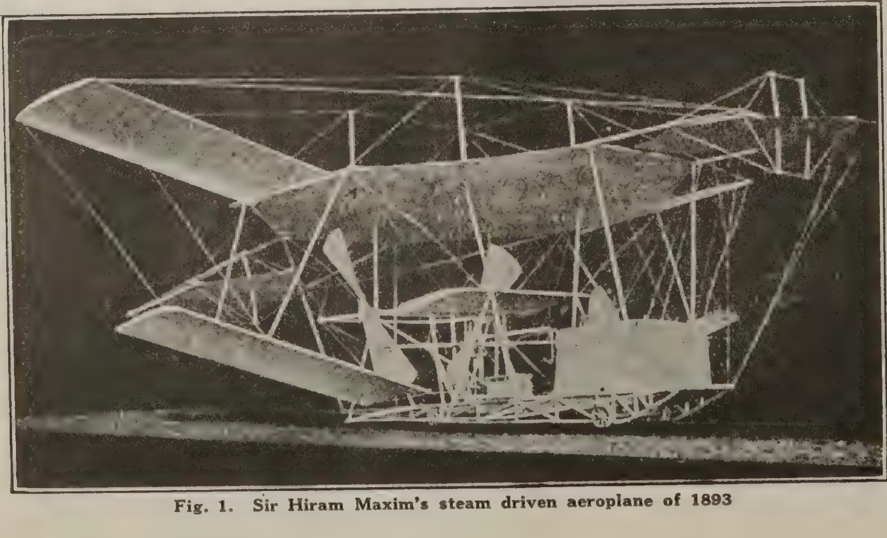

Fig. 1. Sir Hiram Maxim's steam driven aeroplane of 1893

* The Westinghouse Machine Co.

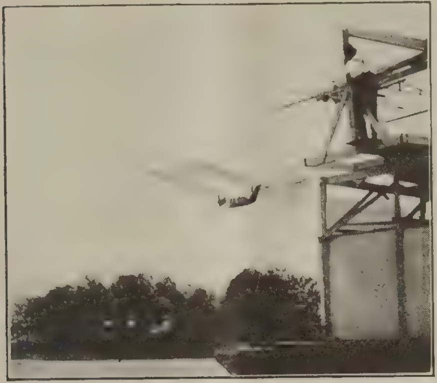

Fig. 4. Prof. Langley's steam driven model just after launching

Out of all the experimental development of nine years of strenuous work, there was evolved a steam driven model known as No. 5, which had a wing spread of 13 feet, and which weighed 26 pounds complete. On the afternoon of May 6, 1896, this model was launched over the Potomac River with a steam pressure of 150 pounds, and started directly ahead into the gentle breeze which was then blowing. After launching it slowly descended three or four feet, but immediately began to rise, and at the same time circled to the right and moved around with great steadiness, traversing more than two complete spirals. After the lapse of one minute and twenty seconds, when at a height of from 70 to 100 feet, the fuel was exhausted and the aeroplane gradually descended until it finally touched the water after a flight of one minute and thirty seconds, in which a distance of over 3,000 feet had been covered. This was the first time in the history of the world that a mechanical device produced by man had actually flown through the air under its own power, and had maintained its own equilibrium.

At this point it is interesting to observe that our own government is experimenting with models of a somewhat similar type for carrying high explosives—which models are otherwise spoken of as aerial torpedoes.

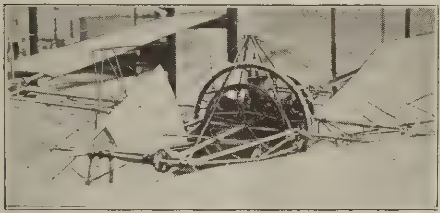

Fig. 6. The five-cylinder radial gasoline engine used in the successful flights of the quarter size model of Langley's man-carrying aeroplane

Fig. 4 shows the model in flight just an instant after it was launched. It was of the tandem monoplane type, with one set of wings in front of the other.

The engine was a single cylinder 1 5/16 by 2¾-inch double acting type with piston valve, and drove the two propellers through bevel gears. It delivered about ¾ horsepower and weighed barely 1 pound. The complete power plant, including engine, flash boiler, pumps, tanks, valves, burners and piping, weighed less than eight pounds, which is under 11 pounds per horsepower; an exceedingly creditable result.

The mechanism at the right is the launching device mounted on the roof of the houseboat. Mr. Langley started all his power driven aeroplanes from a sort of catapult, in which the aeroplane was held to a carriage running on a track and was released after traveling the length of the track under the impulse of coil springs. Langley's large man-carrying aeroplane, Fig. 5, which was tried out in 1903, was launched from a similar device, and failed to make successful flights on account of some accident which tripped the machine just as it was leaving the car and threw it into the water.

This happened twice, and caused so much ridicule in the press that Mr. Langley was unable to get any further financial aid. He died in 1906 without having had the satisfaction of seeing his aeroplane fly. A few years ago Glen Curtiss repaired this aeroplane and by fitting it with pontoons so that it could rise from the water, was able to make a very pretty flight, proving it to have been the first absolutely successful man-carrying aeroplane ever built. What a pity it is that Mr. Langley was not able to see that flight!

It will be recalled that the Wright brothers used a launching device operated by falling weights in all their early experiments, and a similar catapult is now used for launching aeroplanes from battleships in our navy.

As an outcome of this successful model and another similar to it, President McKinley became interested in the military possibilities of aircraft, and in 1898 caused the Board of Ordnance and Fortifications of the War Department to authorize and finance the construction of a man-carrying aeroplane under Mr. Langley's direction. It was decided that the new machine should follow the general type of the models as far as practicable because heartrending difficulties experienced during the preceeding eleven years had taught that even a slight departure from the type that had proved successful, might be very costly.

The great difficulty to be overcome with the large machine was the power plant, which even today is the source of the greatest troubles with aeroplanes. The possibility of using steam was seriously considered because of its success on the models, but it was decided that in order to get a plant light enough it would be exceedingly delicate, and the internal combustion engine which was just coming into prominence in automobiles, seemed to offer a more satisfactory solution. At that time practically no thought was given to efficiency because flights of sufficient duration for the weight of fuel to become serious, were not yet considered seriously. If they had been, but little attention would have been given to steam because the most efficient practical steam plant of small size which has yet been constructed, uses twice as much fuel as the best modern internal combustion engines. Even for very short flights where fuel weight is not important, the weight of boiler, condenser, pumps, etc., even in Maxim's phenomenally light plant, was over twice as heavy as Langley's large internal combustion engine which was made later. For this reason it is astonishing to hear rumors at present of responsible organizations contemplating the use of steam turbines for aeroplanes. The turbine itself can be made very light, but the weight which would be saved over a reciprocating engine, would be lost by the weight of the reduction gear required to drive the propeller at the proper speed.

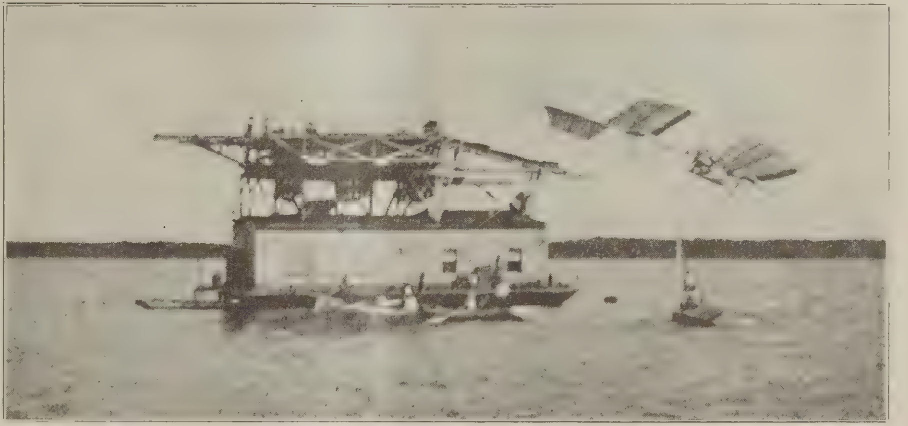

Fig. 5. Langley's man-carrying aeroplane

In December, 1898, a contract was signed with an engine builder in New York City to supply a twelve horsepower engine weighing not more than 100 pounds, delivery to be made in six and one-half weeks. Strange as it may seem to modern engine builders, the engine was completed before the elapse of the contract time,—but it was impossible to get it to deliver more than 4 horsepower for some unaccountable reason. It was the first air-cooled revolving engine ever built, and the problems which developed were too much for the builder. A quarter size model have fixed cylinders with cooling ribs, performed excellently. But in the mean time European engine builders were interviewed with the hope that some one of them would undertake the construction of a satisfactory engine. Everywhere the builders said that they did not care to undertake the work, and that they did not consider it possible to construct an engine of 12 horsepower weighing less than 200 to 300 pounds, and that, if they had thought it possible, they would already have done so, as they had had numerous inquiries for such engines. In spite of the discouragement Mr. Charles Manly, who was assisting Mr. Langley, offered to undertake the construction of the required engine from the parts of the unsuccessful engines built in New York.

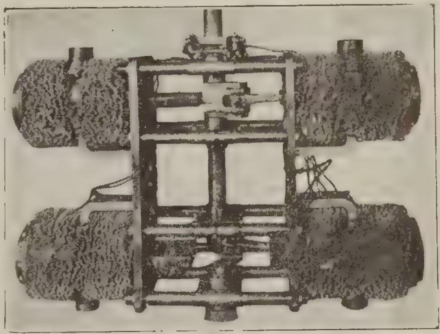

Fig. 8. One of the Freak air-cooled gasoline engines developed while the art of flying was very young

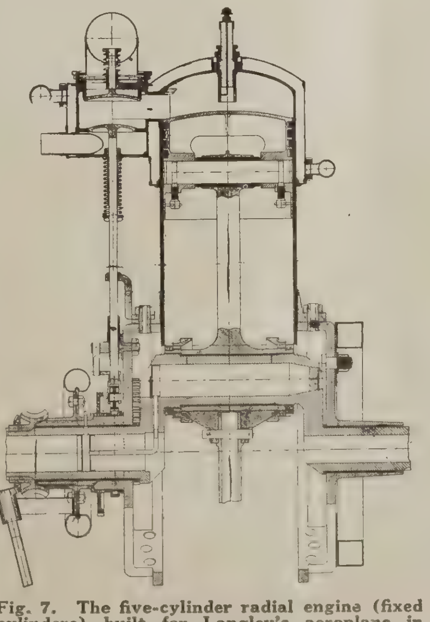

Fig. 7. The five-cylinder radial engine (fixed cylinders) built for Langley's aeroplane in 1901

The five cylinder water-cooled radial engine shown in Fig. 7 was the outcome of his efforts. Each cylinder of this engine was drawn from a 3-16 inch steel plate by Mr. Joseph Stimmetz, and machined inside and out, leaving a 1-16 inch shell. To this shell was brazed the valve chamber which had been machined from a solid forging. The jackets of sheet steel only 0.020 of an inch thick, were brazed on by Mr. Manly himself, since no one could be found who would undertake the work. In spite of the trouble involved, it was less difficult than to deposit copper jackets electrolytically, so undeveloped were these processes only fifteen years ago. In order to minimize the lubricating difficulties which might have been experienced if the pistons were to bear directly against the steel cylinders, cast iron liners 1/16 inch thick were shrunk in. Even though engine builders had declared such construction impractical, if not impossible, no trouble was ever experienced with these liners, and they served their purpose admirably. The difficulties encountered in attaching five connecting-rods to one crank-

THE G. V. MONOSOUPAPE GNOME

WHAT American enterprise and workmanship can accomplish when the gauntlet is thrown down is evidenced by the performance in actual warfare of the first one hundred American built Gnome Monosoupape engines shipped to the British Admiralty. In material and workmanship, as well as in developed horsepower, they were pronounced equal in every way to similar engines produced after years of specialization in France and England.

Rotary aeroplane engines, and particularly those of the Gnome type, are used almost exclusively in scout and pursuit planes. The Monosoupape (single valve) Gnome, the American rights for which are controlled by The General Vehicle Company, Long Island City, is of 100 h.p. at 1,200 r.p.m. and develops great speed. It has nine cylinders.

The Gnome originated in France about eighteen years ago and mechanically is one of the most beautiful, if intricate, of all aero motors. The workmanship necessary for its manufacture is so fine that before the war made thousands of light speed planes necessary, its successful production in America was thought out of the question.

Think of producing an aeroplane engine which will give one horsepower for every 2.7 pounds of weight and you will have some idea of the fine alloy steels necessary to start with. The selection of the proper materials alone consumed over half a year before orders for these were placed, and even to-day, after manufacturing scores of such engines accepted for export, the metallurgists of the General Vehicle Company test every forging.

It is American capacity for fine workmanship of this class which is worrying those officials at Washington who appreciate the demands which war would make upon us. The experience necessary to perfection is often a question of years. Shell production is in most cases child's play compared to the manufacture of high grade aero engines of the rotary type. Yet these are necessary for the high speed planes now recognized as absolutely essential in air supremacy.

The Gnome is the scout of the air fleet. Planes equipped with stationary engines excel in their field, but light weight coupled with high speed is what makes the scout plane possible. As evidence of the elimination of weight on the Monosoupape Gnome study these figures: The forging from which the distribution case is made weighs 201 pounds; the finished case (all one piece), 15½ pounds. The cylinder forging, 88 pounds; the finished cylinder, 5½ pounds. The "mother" rod, that odd looking integral piece to which are secured the other eight rods, is reduced from 21 to 5½ pounds. The nine cams, weighing a few ounces each, have a tensile strength of 264,000 pounds to the square inch. The entire engine calls for work within 4/10,000 of an inch.

The sole American rights for the 100 h.p. Monosoupape Gnome engine have been secured by the General Vehicle Company under arrangements with the Gnome & LeRhone Engine Company of London. The United States Government, after inspecting many of the G. V. built engines ready for shipment abroad and checking up their performances on the other side, purchased over one hundred engines for army and navy use.

While great things are expected of other types of American built engines, Government officials have expressed themselves as highly gratified to know that no great difficulty will now be experienced in obtaining highly efficient engines of the rotary type manufactured in this country. It is understood that plans are under way for the extensive manufacture of Monosoupape type engines for school purposes as well as for export to neutral and belligerent countries. In any event American skill has added another banner to its collection and another brick to the wall of industrial progress.

Diagrammatic explanation of the operation of the nine-cylinder Gnome engine

GENERAL DESCRIPTION

Construction—The construction of the "Monosoupape" (or single-valve) engine of both types is practically identical. Type A is an 80 h.p. seven-cylinder engine, and Type B is a 100 h.p. nine-cylinder engine. These engines have the same bore and stroke, *viz.*, 110 mm. and 150 mm., respectively.

The cylinders, valves, etc., of both types are interchangeable. The following description refers particularly to the Type B2 engine, of English manufacture, without control mechanism, but can be taken as applying generally to both types.

Characteristics—The characteristics of the "Monosoupape" engine, as compared with the ordinary Gnome engine, are:

(*a*) Absence of inlet valves.
(*b*) Solid piston heads.
(*c*) No carburetor.
(*d*) Non-explosive mixture in crankcase.

DESCRIPTION

The crankcase of the engine is made in two halves, fastened together by bolts, the two halves clasping the cylinders at their base. The cylinders are prevented from turning in their setting in the crankcase by keys.

Each Cylinder is drilled near the bottom with a number of circular ports connecting the interior of the crankcase with the cylinder.

The Ports are uncovered by the pistons near the bottom of the stroke, permitting a passage from the crankcase to the cylinders.

The Exhaust Valve and seating is fixed at the extreme outer end of each cylinder by means of the usual castellated ring nut. The weight of this valve is so adjusted that its centrifugal action, when the engine is rotating, is equal to that of the tappet rod and lever; and thus the use of counterbalance weights, such as are fitted to the rocking levers of the ordinary Gnome engine, is avoided.

The System of Connecting Rods is similar to the ordinary Gnome engine, and is composed of one master rod and eight small rods.

The Crankshaft, which is hollow, is in two parts, but the smaller half can be dismantled from the front of the engine. The rear or large end of the hollow crankshaft is open to admit air and contains the petrol jet, whilst the front nose extension is closed.

The gasoline is supplied from its reservoir to a union on the crankshaft, then passes along the copper pipe 30577 to the elbow 30717. The jet 30705 which projects into the crankcase is held on to a nipple with a ground conical seat by the screw 30706. It has eight holes which project the petrol downwards in the direction of the flow of mixture towards the opening ports in the cylinder.

The Camshaft, which is fitted at the small end of the crankshaft, turns at half the speed of the engine and in the same direction and is operated by the usual satellite pinions.

Lubrication is by means of the usual Gnome pump, and the oil-way system is similar to the 80 h.p. Gnome engine, except that there is a forced feed to the gudgeon pins.

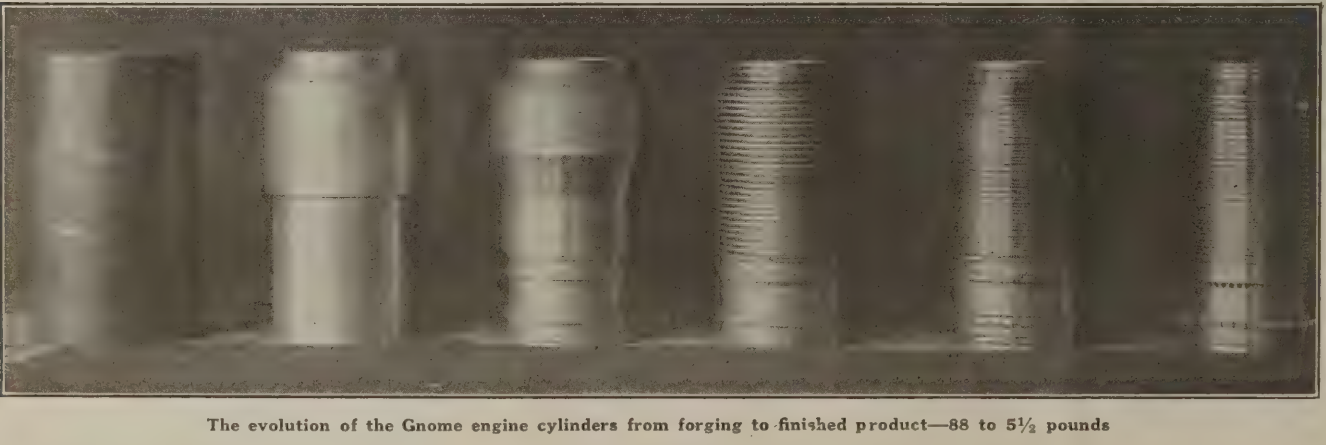
CYCLE OF OPERATIONS

The engine works on the four-stroke cycle. Consider a cylinder in which the piston is on the compression stroke and follow the engine through two revolutions.

(1) *Ignition*, which is "fixed," is set to take place 15° to 20° before the top dead center.

(2) *Working Stroke*—After ignition the piston descends on the working or power stroke, as shown by the arc B C (Fig. 2).

(3) *Exhaust Stroke*—When the cylinder has turned through 85° from the top center, the valve begins to open, and exhaust of the products of combustion commences (Fig. 2, C). The exhaust stroke continues until the piston returns



The evolution of the Gnome engine cylinders from forging to finished product—88 to 5½ pounds

(Continued from page 257)

pin without sacrificing necessary bearing area, were solved by the use of a master rod, in which construction one rod has a sleeve around the whole crank-pin, as is usual with single cylinder engines, and the other four rods bear on the outside of this sleeve. In this way the small bearings between the four rods and the master rod receive none of the rubbing effect due to the rotation of the crank-pin, except that of slipping a very short distance over the sleeve during each revolution, on account of the angularity of the rods. This construction was successful from the start and is now used in a slightly modified form in nearly all radial and revolving engines.

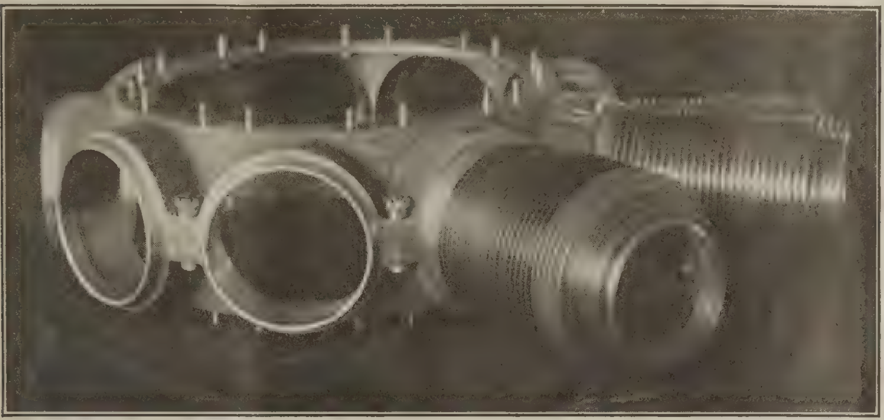
In order to get a reliable and equally hot spark in each cylinder, the scheme was originated of using one spark coil and vibrator for all cylinders, with a distributor to select the correct cylinder for each spark. All procurable spark plugs were very unreliable because of the frequency with which they became short-circuited with carbon, and to correct this the plug shown in this drawing was made. The pocket around the points which is now known to be so valuable, eliminated all this trouble.

As may be seen, the intake valves are automatic, and the exhaust valves are operated from a central cam. This cam, which has two points 180° apart, rotates at one-quarter engine-speed in the opposite direction. The light weight of the whole valve mechanism is noteworthy. As all parts were lubricated by oil cups, very little unnecessary oil was used, giving a consumption which is superior to what is usually required by such engines.

This engine, which was completed in December, 1901, was given three ten-hour runs while connected up to water dynamometers and showed a performance which is not often surpassed even to-day. At 950 r.p m. 52.4 horsepower was delivered, giving a weight of but 2.37 pounds per horsepower, based on the stripped weight of the engine, which is 124 pounds. The complete engine, including balance weights, ignition coil and batteries, carbureter, radiator, water and gasoline tanks and all other accessories, and with radiator, water tank and jackets filled with water, is only 3.65 pounds per horsepower. This is about on pound per horsepower lighter than present day water-cooled engines.

Thus two Americans succeeded in producing the first man-carrying aeroplane which could support its own weight in stable flight; Samuel Langley produced the aeroplane, and Charles Manly produced the power plant. Those of us who blush with shame because our government possessed less than fifty military aeroplanes at the outbreak of the European war, while European countries were making daily use of tens of thousands, will do well to realize that this first successful aeroplane was developed by the support of our own military authorities long before other governments did as much, and that if it had not been for the ridicule of a hostile press, and the sneers of a self-satisfied public, our government would have been the first to have possessed practical military aeroplanes.

(To be continued)

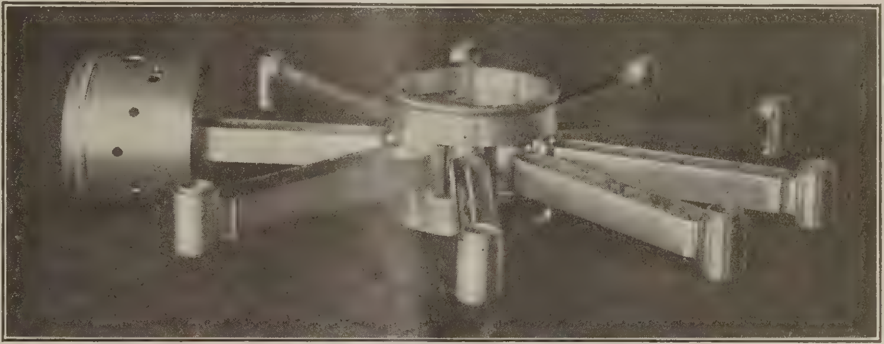


The two-piece crank case, showing the manner in which the cylinders are held in position

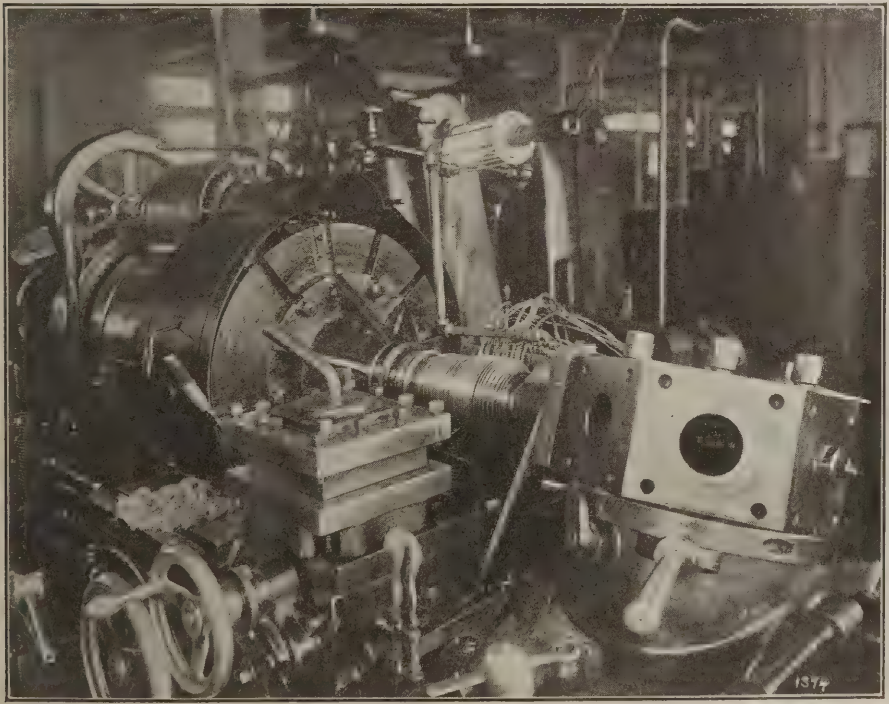
to the top dead center, as shown by the arc C D E F.

(4) *Induction Stroke*—The valve still remaining open, the piston descends on the induction stroke, drawing air into the cylinder through the valve. 65° before the bottom center the valve closes (H, Fig. 2). On the piston continuing to descend, a partial vacuum is created in the cylinder until it is 20° from the bottom center (I, Fig. 2).

At this point the piston uncovers the ports in the cylinder wall, making connection between the cylinder and the crankcase, and a very rich petrol mixture is drawn into the cylinder. This rich mixture is diluted by the air already in the cylinder, and the resulting mixture in the cylinder is a good combustible gas.



The arrangement of the "mother" rod and the other rods on the hub



One of the thirty operations in the turning of the cylinders; cutting the fins on a heavy-duty lathe

The ports in the cylinder will remain uncovered until the piston reaches the point J (Fig. 2) on the return stroke.

(5) *Compression Stroke*—On the closing of the ports the piston ascends on the compression stroke J (Fig. 2), and when 20° from the top center (L, Fig. 2) ignition occurs, and the cycle of operations is repeated.

Note—The timing diagram given in Fig. 2 is an average from a number of tests. It is found that engines vary slightly, and each engine is supplied with a special set of timing figures which should be used and adhered to.

(Continued from page 259)

down by Russian motor-guns on Jan. 26th, 1915 while raiding Libava. The crew of seven were made prisoners.

No definite information is available regarding the number of airships turned out during the war; it has been reported that the L. F. G. works of Bitterfeld have been turned into a repair station for Zeppelin airships and that the output of Parsenal airships has consequently been greatly limited.

FOREIGN NEWS

FRANCE

The official report for April 26 is as follows:

"April 23 and 24 six German aeroplanes were brought down in aerial engagements by our pilots. In addition sixteen were seen falling into their own lines, seriously damaged.

"From the 16th to the 22nd our pilots added appreciably to the number of their exploits. Sub-Lieut. Dorne brought down his nineteenth and twentieth machines; Sub-Lieut. Geuillin his fourteenth; Lieut. Pinsart his ninth and tenth; Sub-Lieut. Tarascon his tenth; Sub-Lieut. Languedoc his sixth and seventh, and finally, Adjutant Lufbery (Raoul Givas Lufbery of the American Squadron) accounted for eight machines up to that day."

Paris, April 29.—American aviators again have emerged victorious from a battle in the clouds with German airmen, it was learned here to-day. The heroes of the encounter were Willis Haviland of Minneapolis and Charles C. Johnson of St. Louis, who are under the command of Lieut. William Thaw.

Flying together in separate machines, the two Americans encountered a group of German aeroplanes. Haviland forced one enemy craft to an altitude of 4,000 feet, where he engaged it in combat. After a spirited fight the German machine, riddled by machine gun fire, collapsed and fell.

Almost at the same time Johnson had a desperate battle with another German machine, which he put to flight, evidently in distress. Its fate was not determined. Several other German aircraft refused battle and escaped.

The *Matin* says news has been received at British headquarters that Lieut. William Leefe Robinson, the aviator who destroyed a Zeppelin, is not dead but a prisoner in Germany. Lieut Robinson's gasoline ran out and he was obliged to land within the German lines.

A German official statement received in London April 13 said Lieut. Robinson's machine was shot down on April 5 by a German battle aeroplane. Lieut. Robinson won the Victoria Cross by bringing down a Zeppelin during a raid on London last fall. It was the first feat of the kind to be performed in the war.

GERMANY

A recently captured report of Gen. von Buelow on the experiences of the German First Army has instructive passages, especially where he dwells upon British superiority in the air, how airmen attack the German infantry in their trenches with bombs and machine guns. He adds:

"Even though the losses thus caused are comparatively small, the occurrences have an extremely lowering effect upon the morale of our troops, who at first were helpless. The innumerable balloons, hanging like grapes in clusters over the enemy lines, produced a similar effect, for individual men and machine guns could be picked up by them, watched and subjected to fire."

German seaplanes on April 26 successfully bombed the harbor works at Sulina (in Roumania, on the Black Sea, at the mouth of the Danube, near the Russian border). Large fires broke out in the harbor works and on barges. All the seaplanes returned safely in spite of the vigorous firing of anti-aircraft guns.

The destruction of a Zeppelin of the latest type is reported in an Amsterdam dispatch to the Exchange Telegraph Company. It is said Prussian deserters who have reached Maestricht, Netherlands, told of the loss of the airship, which was destroyed in a storm when east of Duisburg, Rhenish Prussia, on a trial trip between Friedrichshafen and Wilhelmshaven last Monday. The airship was overturned by the gale and exploded, causing the death of the entire crew and two officials from the Zeppelin plant.

GREAT BRITAIN

London, April 24.—A British Admiralty statement reports an attack by three British naval air machines on five enemy destroyers which were sighted on April 23, steaming between Blankenberghe and Zeebrugge in a northeasterly direction five miles off the coast.

"The leading machine," says the statement, "attacked, dropping sixteen bombs, one of which was seen to obtain a direct hit. The remaining four destroyers scattered and were attacked by the two remaining machines, thirty-two bombs being dropped. The leading destroyer was observed to take a list to port and remained stationary after all the bombs had been dropped.

"The four destroyers closed in on the disabled craft. A hostile seaplane attacked our machines, but was easily driven off. At 6:10 P. M. the four destroyers were reported by a reconnaisance machine as entering Zeebrugge Harbor. It is considered most probable that one destroyer was sunk."

Announcement was made in the House of Commons on April 26 by Major John L. Baird, representative in the House of the Aerial Advisory Board, that the Government had decided to appoint a committee under the chairmanship of Lord Northcliffe to investigate civil aerial transport after the war. This, he said, would permit of the employment of the large number of skilled pilots and the aeroplanes in the hands of the army and navy, and the still vaster number of machines the construction of which is under way or planned. Although Major Baird did not disclose the exact figures, he showed that the output of aeroplanes had been increased greatly during the last few months and that an even greater increase was expected. Taking the monthly average output for the last year as the imaginary figure of eight, he said, the output for the first two months of this year would be represented by sixteen, and it was expected that by the end of the year it would be represented by thirty-eight.

The exploits of the Allied aviators during the past week have excelled in intensity and results all previous manœuvers. To tell the entire story would require pages, but we will take one day—April 24—as an example. The report follows:

With the British Armies in France, April 24.—The intensely bitter ground fighting of the last two days has been reflected in the air, and the British Royal Flying Corps yesterday established a new record by bringing down forty German machines. Fifteen of these were actually seen to crash, while twenty-five collapsed or fell in spinning nose dives, completely out of control.

The fights took place 15,000 feet in the air, from which distance it is barely possible to see the ground and wholly impossible to see an adversary crash unless the pilot deliberately follows down. Such a course is not feasible where the fighting has taken on the character of a general melee, as is nowadays often the case. A remarkable part of yesterday's performance is that only two British machines are missing.

It was the finest day for war flying that the young khaki pilots ever had, and to-day they have been at it again since sunrise, but the full reports of their exploits are not yet in. It is known, however, that one intrepid young flyer, failing to find a single German observation balloon aloft, sought out one in its hangar on the ground, dived at it and set the big gas bag ablaze from stem to stern.

Since Sunday the British airmen have been revelling in weather they have long desired. Not a cloud was in the sky to-day behind which a German could find shelter. Deprived of that means of "digging themselves in," the German flyers were far scarcer than usual and very difficult to find. British machines were everywhere along the battle-front and far behind the German lines. Bombing raids were carried out forty-five miles back, the machines deliberately flying over ground where battles were raging with the greatest fury.

German trains rushing reinforcements to the front were attacked and transport columns on the roads were bombed and completely disorganized. In several instances the British went low over the fighting lines and poured machine gun fire into the German ranks. In doing this machines have deliberately crossed the fire of their own as well as the enemy's guns.

Yesterday one British pilot, after bringing down two Germans and exhausting his ammunition, descended, reloaded, filled up his petrol tanks and took to the air again. Within half an hour he had brought down his third machine for that day. Another pilot felled two machines, while the other thirty-five were divided among a similar number of British pilots.

The greatest fight yesterday, oddly enough, was a drawn battle. One of the British pilots met a brilliant German flyer, and for a full hour they manœvered in a most marvelous manner, without either being able to bring his gun to bear on the other. They rolled, looped, twisted, deliberately stalled their engines, and, standing the machines on their tails, slid backward through the air; but all to no avail. It was probably the most wonderful air duel the war has yet seen.

The British pilot reported to-day that several times he felt sure he would get his adversary between his sights, but the latter invariably wriggled out of the line of fire. The British flyer himself was kept busy avoiding the German, and once he had to dive almost perpendicularly. The combat did not break off until both pilots had fairly exhausted themselves and their petrol.

Strangely enough, later in the day another British pilot encountered the same German machine. The Britisher was winging his way home after a hard day's work, but he jockeyed with the German for nearly a quarter of an hour before flying on.

In strange contrast to this was the experience of one British pilot, who somewhat peevishly complained last night that "I only got a 'rabbit.'" He explained this by saying that, while his opponent had a good machine, he was a clumsy fellow and couldn't fight at all, and was sent spinning with the first burst of gunfire.

Still another pilot mounted a fast, new machine and deliberately allowed a German to get on his trail. Then he suddenly looped behind his adversary and caught him just within the sights, the burst of fire killing the German instantly. The machine swerved and the dead man pitched out ten thousand feet from the ground.

The fighting yesterday was all within the enemy territory. Several British machines had bullet holes through their wings, but sailed home unaided and took the air again this morning.

ITALY

Udine, Italy, April 28.—Several thousand copies of President Wilson's war message, translated into the different languages of the Austro-Hungarian monarchy, have been dropped by Italian aviators in Austrian territory.

JAPAN

Japan has lost another promising young army airman by the death of Lieutenant Sugino. Previous to his return journey from Shimoshizu, Lieutenant Sugino discovered some flaw in his machine, so delayed his start for Tokorozawa. Eventually he commenced what proved his last flight at 10:40 A. M. About 11:25, when the machine was over Okumura, Toyoshimagori, it was seen to turn over two or three times and then crash to the ground.

An employe of the Inawashiro Water Power Company was an eyewitness of the catastrophe, and hastened to the scene. Lieutenant Sugino was found pinned beneath the wreckage of the machine. The unfortunate officer was immediately removed to a house close by and made as comfortable as possible, but he lived but a short time.

On learning of the accident, officers of the Flying Corps at Tokorozawa, including Commander Narutaki and Captain Tokugawa, hastened to the scene by motor-car, but arrived after Lieutenant Sugino had breathed his last.

The northeast wind is alleged to have been responsible for the accident, breaking the right wing of the machine. The propeller then came into collision with the loose end of the wing and tore the machine to pieces. The late officer was about to take an examination to enter the army university, and was to try to obtain his certificate for flying in a few weeks' time.

Lieutenant Sugino, who was twenty-seven years old, was born in Kanazawa, and it is told that by the death of the lieutenant the city of Kanazawa has lost three military aviators hailing from there. H.I.M. the Emperor, upon the news of his death, dispatched an Imperial messenger to express sympathy, and H.I.H. the Crown Prince also sent a representative. The monetary gift was conferred on the family of the aviator by the Emperor and the Crown Prince. The Emperor also granted him posthumous honors, which decorated the deceased with the Fifth Order of Rising Sun with double rays.

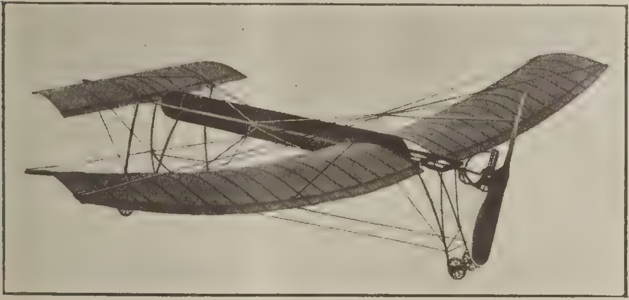
Compressed Air Driven Model

The development of the compressed air engine has given an added impetus to model making, necessitating more scientific experimenting and developing the act of model flying along lines of greater value to those who may eventually take up the work of building our future air fleets.

In the accompanying illustration is shown a model aeroplane of monoplane type driven by a three-cylinder rotary engine which was constructed by Edward Willard Dart of South Norwalk, Connecticut.

The engine was constructed after several months of patient labor. Careful judgment was exercised in the drafting of the plane and likewise in the assembling of the engine for it is absolutely essential that all parts be properly fitted as to enable the engine to run smoothly. In designing the wings every detail was taken into consideration to insure good flying.

The main wing has a spread of 58 inches and 7 inches in chord. The elevator measures 23 inches in spread by 6 inches in chord. In the construction of both wings bamboo ribs are used the frames being covered over with China silk and coated with Celluloid solution. The main wing is made in two sections to facilitate quick adjustment to the fusilage.



Model by Edward Willard Dart

Paper Models

Mr. H. Major writes as follows concerning paper models:

"I am sending scale drawing of a small paper monoplane, which I have found to give excellent results. The scale given only applies to diagrams illustrating wing construction, side elevation and plan view.

"Materials to be obtained before commencing are:—

"1. A few sheets of hard bank paper; if this not to hand, fairly stout notepaper may be used.

"2. A small piece of thin tinned sheet iron.

"3. A short length of iron wire of about 26 S.W.G.; a thin hairpin will serve the purpose.

"4. A piece of wood 8 ins. by 1/6 in. by 1/10 in., to form the backbone, and another 5 ins. by 2/5 in. by 3/10 in., for the screw.

"6. A few small glass beads, the smallest procurable.

"7. A thread or so of silk; a tube of liquid glue; 10 ins. of 3/16 in. elastic; scissors, &c.

"Take the wood intended for the backbone, and taper slightly towards each end, leaving a full section in the center. The rubber hook should be fitted at one end, as illustration C and C1, in such a manner that it will allow the rubber to run along the thickness of the wood (not the width). The piece of tin should then be taken and drilled, so as to allow the wire to just pass through the hole.

"The metal may now be cut with the scissors to the shape B, and bent at the dotted lines as in B1, this bearing to be fitted to the opposite end of the backbone, and the flaps folded over as B2. A thin piece of cane, 4 ins. long, should be taken and bound to the backbone at C, in the manner shown in C1. This is set at a slight upward angle, and is to carry the tail.

"The tractor screw may now be carved. Mark the wood in the center of its length and width, and bore a hole with a needle through the thickness. Carve the propeller so that the angle of its blades diminishes towards the tips. Sandpaper till almost as thin as paper and coat with liquid glue. This will soak in and dry with a rough surface, so continue coating with glue, until a varnished effect is obtained. A screw treated in this manner will very rarely break, and when thoroughly dry, is not rendered sticky by the heat from the fingers. Pass a piece of wire 2¼ ins. long through the hole in the boss, and bend over at the end as B2. Place two beads on the shaft, and bend same at the other end into a hook for the rubber.

(To be continued)

Kites

The official Gazette reports the following kite patent which has been allowed and for the information of our kite friends the report is herewith printed in full:

1,223,163. KITE. Andrew Lang Graham, Santa Rosa, Cal. Filed Dec. 14, 1916. Serial No. 136,956. (Cl. 244—23.)

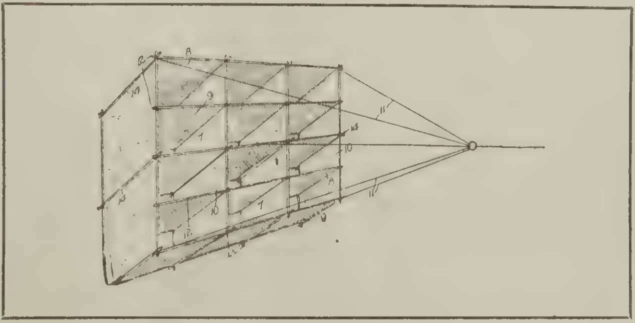
1. A kite comprising a cell having a rectangular-shaped opening in the front and rear thereof and presenting rectangular-shaped top and bottom planes and parallelogram-shaped side planes, said side planes being so related to the top planes that the free front edge of said top plane overhangs the free front edge of the bottom plane in the projection of said top plane on the bottom plane.

2. In a multicellular kite, a plurality of coplanar cells each presenting a substantially rectangular-shaped front and rear opening, each of said cells having substantially rectangular-shaped top and bottom planes and substantially parallelogram-shaped side planes.

3. In a kite, a plurality of cells, each cell presenting a front and rear opening, the top and bottom planes of each cell being in the shape of a rectangle, the side planes of the cell being in the shape of a parallelogram, the front and rear of said cells lying in respectively common planes.

4. In a kite, a plurality of coplanar cells open in the front and rear thereof, each cell presenting rectangularly-shaped top and bottom planes, and parallelogram-shaped side planes, said side planes being so related to the top and bottom planes that the front edge of the top plane overhangs the front edge of the bottom plane and the rear edge of the bottom plane extends beyond the rear edge of the top plane.

5. In a kite, a plurality of coplanar cells open in the front and rear thereof, each cell presenting a rectangular-shaped top and bottom planes and parallelogram-shaped side planes, transverse and vertical bars reinforcing said cells at the front and rear, brace members connecting said bars, and bridle strings connected to said brace members at predetermined points of the kite, substantially as and for the purpose set forth.



Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Newark, Feb. 8.

Dear K. C. B.—We have a hydroaeroplane over here in Newark that spreads its wings 73 feet. We want you to come over and make a flight with one of our aviators, and we can assure you that the pleasure of having you over will only be exceeded by the exhilaration of your flight. If you will come, will you kindly let us know when to expect you?

N. Y. AERO CONSTRUCTION CO.,
Henry Frauenthal, Secretary.

LISTEN, HENRY.
* * *
ONE TIME before.
* * *
OUT IN the West.
* * *
I PROMISED a fellow.
* * *
I'D GO for a ride.
* * *
IN AN aeroplane.
* * *
AND I got in.
* * *
IN FRONT of a lot of people.
* * *
AND THEY tied me there.
* * *
WITH STRAPS.
* * *
AND I was scared to death.
* * *
AND THE aviator.
* * *
HE GOT in his seat.
* * *
AND THEY tried to start it.
* * *
AND THEY couldn't.
* * *
IT WOULDN'T work.
* * *
AND THEY unstrapped me.
* * *
AND LET me out.
* * *
AND I'VE always figured.
* * *
IT WAS the Lord.
* * *
THAT FIXED the engine.
* * *
SO IT wouldn't go.
* * *
HE WANTED to save me.
* * *
FOR SOMETHING else.
* * *
NOT SO violent.
* * *
AND ANYWAY.
* * *
ALL YOU ask me to do.
* * *
IS TO make a flight.
* * *
AND YOU don't say anything.

ABOUT LANDING.
* * *
AND FROM what I've seen.
* * *
IT'S THE landing.
* * *
THAT COUNTS the most.
* * *
IF I wanted.
* * *
TO MAKE a flight.
* * *
I COULD do it.
* * *
WITHOUT ANY aeroplane.
* * *
OR ANYTHING.
* * *
I COULD go to the tower.
* * *
OF THE Woolworth building.
* * *
OR THE Brooklyn Bridge.
* * *
OR ANYWHERE.
* * *
AND JUMP off.
* * *
IT ISN'T the flying.
* * *
THAT SCARES me.
* * *
IT'S THE looking down.
* * *
AND WONDERING.
* * *
AND AT this time of the year.
* * *
IT'S SO much worse.
* * *
THAN THE Summer.
* * *
THE GROUND'S frozen.
* * *
AND IT doesn't give.
* * *
AND I don't want you to think.
* * *
THAT I'M a coward.
* * *
BECAUSE I'M not.
* * *
BUT I like to be.
* * *
WHERE I can run.

IF I have to.
* * *
AND THE way I'm built.
* * *
I CAN'T run.
* * *
UNLESS MY feet.
* * *
ARE ON the ground.

AND I thank you.
* * *
FOR YOUR invitation.
* * *
BUT I can't go.
* * *
MY WIFE won't let me.
* * *
I THANK you.

Explaining It to Him

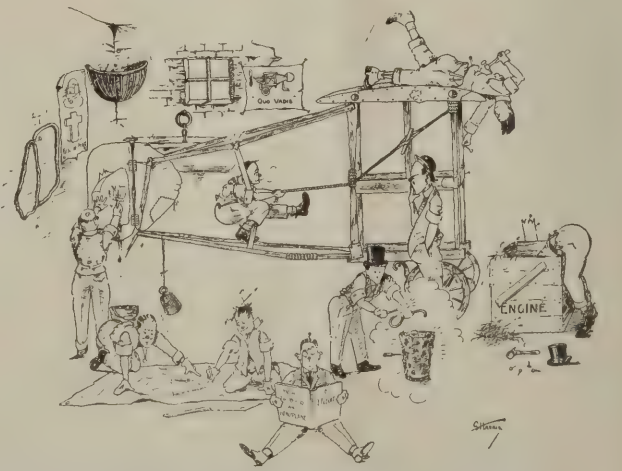
They were standing together in front of the aeroplane. It was evident that one of them knew all about such machines, while the other wouldn't have been able to describe one of them if it had driven up to him upon horseback.

Removing a sign from the machine which said, "Please do not lean on wings," one of the men, with an ease worthy of special commendation, placed his elbow on the center of the highly varnished wing surface, and began to talk.

"Yes, sir," he said, "I know all about these machines. This one here is a tractor biplane. Why a tractor? Why that is because they use one of those farm tractor engines in it. You see those three wings? Well, that's why it is called a biplane, for, as you may know, the word *bi* is from the Spanish, and means *three.* You see this feller Zeppelin, that invented the aeroplane, was a Spaniard, and as he spoke Spanish they naturally followed his wording."

He then stood off from the machine a few feet and gazed at it admiringly. "You see that long body, that goes straight back? That's where they keep the gas. These things can't fly without gas. How does it go up and down? Very simple! You see, when they want to go up they point the thing up in the air, and it just goes up. To come down, they let the gas out and it just naturally comes down. How do they steer them? Lissen, I'll explain. You see those wheels underneath? Well, when they want to turn, they simply turn the wheels the way they want to go, and the whole machine turns with the wheels. Could anything be more simple?"

His friend looked at him in open-mouthed wonder and admiration, and they left.



Scenes in an Aircraft Factory, Ill. Before the war—when it may be noted, the experimenters were gentlemen, as the top hats will witness, or lunatics (vide the designer).

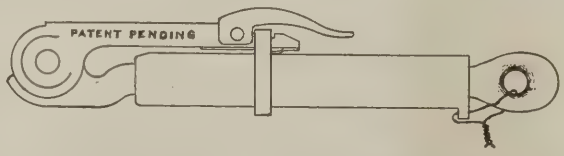
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

For Your Flying Boats Use

Adopted by the U. S. Aeronautical and War Departments.

All the prominent builders of flying boats use this glue in combination with linen between the veneer of the diagonal planking on all their flying boats, pontoons and floats. It is not only waterproof and elastic but will waterproof and preserve the linen indefinitely. Experience has shown that when this glue is used, owing to its elasticity, the inside layer of diagonal planking will remain perfectly water tight although the outside layer may be badly broken.

Burgess Primary Training Tractor Type B. P.

This machine was designed by W. Starling Burgess at the request of the United States Army for a primary training tractor aeroplane having a practical side by side seating arrangement with duplicating controls.

This has been accomplished without sacrificing in the least the efficiency or appearance of the machine.

It fills the urgent need found at present in the aviation schools—giving great range of control and allowing the instructor to be at side of the pupil during flight, thereby facilitating instruction.

This has proven very satisfactory in experimental flights as well as in the official trials thru which this machine passed with great success.

GENERAL ACOUSTIC CO., 220 WEST 42d ST. NEW YORK

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

The Buck Aircraft & Munition Co., Inc.

Room 327, 42nd St. Building

extensive organization and administrative force. We have been attempting for over a year to do within a few months what should have been done during the past ten years, with a few men. The overburdened Signal Corps in the Army and the Bureau of Operations in the Navy have been trying to attend to the development of aeronautics besides doing their other duties. As a matter of fact, their other duties require more than all of their efforts and all of the time and efforts of a staff many times that of the present one. So we must extend our administrative organizations, and I therefore urge that the time is ripe to establish an independent department of aeronautics, which shall coordinate and develop the aeronautic resources of the Army, the Navy, the Coast Guard, the Post Office, and so forth, and also the civilian developments, including aerial transportation, which is bound to come in the very near future.

In establishing a department of aeronautics, with a secretary of aeronautics, who will be a member of the Cabinet, we shall only follow the example of European countries. Great Britain and France, after trying every means and way, finally had to come to the conclusion that a separate department of aeronautics, with a Secretary of the Air as a member of the Cabinet, was the only solution to the problem. Surely we Americans, who are known to be practical people, will not fail to learn by the experience of these other countries, which are now our allies.

There is now a bill before the Congress, known as the Sheppard-Hulbert Bill, providing for the creation of a department of aeronautics, with a secretary having a portfolio in the President's Cabinet, upon which I hope Congress will act favorably at this session.

How We Can Hit Hard and Fast

(*Editorial in the New York Globe*)

What we can do in air fighting is described in the news columns of this issue. We can hit Germany hard and we can hit her soon. We can establish for our allies complete mastery of reconnaissance and artillery direction. In other words, we can win and hold control of all operations overhead, thereby depriving our enemy of what is vital in modern battles. We can even hope, if we buckle down to the job, to deal German armies a fatal blow by seriously interfering with, if not destroying, their lines of communication.

Destitute though we now are of war planes, there is no reason to doubt that within a comparatively short time our factories can build in large numbers duplicates of the best models of the French and British machines. As it is our allies have been able frequently to assert their superiority in the air on the western front. With the machines we can add this superiority can be made overwhelming and permanent.

As for the crews, our young men will come forward as soon as a call for them is out. We have at least two hundred competent fliers ready to take first shipments abroad. Others can be mustered in and taught the rudiments of aviation while our manufacturers are busy. In the French aviation fields the American corps can be fitted for whatever military service is desirable.

Here is a chance to take part quickly and decisively. It accords with the spirit of the nation that is impatient of needless delay and mere onlooking. If the suggestion meets the approval of the military authorities no time should be lost in getting to work. What America can do to end the war right and soon she wants to do with all her might.

Our Aeroplanes Equal to the Best

(*Editorial in the Jersey City Journal*)

It is not true, as charged by travelers who have returned from the war zones, that Europe has far outstripped the United States in the development and manufacture of the aeroplane, America's own invention. In a report just filed with the Aero Club of America by its Advisory Committee on

SP

YOUR
Valve Department

EVERY development in modern gas engine has found our engineers ready with a valve to meet the new demand.

In co-operation with different aeroplane motor manufacturers we have worked out valves especially adapted to their service.

We can perform the same service for you.

STURTEVANT AEROPLANE CO.
Jamaica Plain, Boston

Aeronautics, a group of distinguished scientists and others who are co-operating with Rear-Admiral Usher in the organization of the Naval Reserve, it is made plain that the American aeroplane is the equal of anything Europe, under the spur of war necessity, has produced. Included on the committee are such men as Rear-Admiral Bradley A. Fiske, retired, Rear-Admiral Robert E. Peary and John Hays Hammond, Jr.

The report sharply asserts that, type for type, the American aeroplane is fully the equal of the European; that our seaplanes are the superior of any; that our speed machines, while attaining 130 miles an hour, against 140 by the crack European makes, discount this small advantage of speed by being 50 per cent safer. Europe's only present complaint against our aeroplanes is that we do not make enough of them.

An investigation of statements of people who on their arrival in this country from Europe have asserted that American aeroplanes are not used at the front in Europe has brought out the fact that the aeroplanes ordered in this country so far, with the exception of our large seaplanes, which are superior to any European product, have been only the training type.

The reason why only the training type of aeroplanes have been ordered in this country by the Allies is that the limited production in this country in the last two years did not permit deliveries of thousands of aeroplanes, and it would have been most inefficient to send to the front a few hundred aeroplanes of a type for which spare parts were not available. This inability on the part of American constructors to deliver aeroplanes by the thousand at the time when the Allies needed them most made it necessary for the different countries to create their own sources of supplies for the bulk of the machines needed by them.

Statements made to the effect that the American fighting aeroplanes do not have the speed and climbing ability of foreign fighting machines are based on the fact that in America we demand a factor of safety of six, whereas foreign machines have a factor of safety of only three. Likewise, where foreign countries accept machines that land at a speed of close to 100 miles an hour, in the United States we expect our fast aeroplanes to land at a speed not exceeding sixty miles an hour.

Considering that we have a factor of safety twice as large as the foreign machines, and that we have a landing speed not exceeding sixty miles an hour, our fighting machines compare favorably with the foreign machines in speed. We get a speed of approximately 130 miles from our machines, while the European machines, with the lower factor of safety and greater landing speed, get only about ten miles more.

America to the German People

LIBERTY BELL

By George Morrison von Schrader

(Mr. A. B. Lambert, president of the Aeronautical Society of Missouri, in transmitting this forceful poem to AERIAL AGE, *through Mr. Alan R. Hawley, suggests that it would be a good idea to translate it into German and have it dropped over the German lines by the Allied aviators.)*

I

Awake, Awake!
For ages you have slept.
Awake, Awake!
The glorious hour now dawns.
Awake, Awake!
Sand up where once you crept.
Awake, Awake!
Refuse to be but pawns.
Rise to your might, be brave and then
Throw down the gauntlet, act as men.

II

Awake, Awake!
Mistake not friends for foes.
Awake, Awake!
Ope wide and clear your eyes.
Awake, Awake!
Then know the author of your woes,
The culprit of your tears and sighs.

III

Learn 'tis not he with whom your swords are crossed;
His purpose lies alone in setting free.
Quick grasp the outstretched hand before 'tis lost,
That beckons on to glorious liberty.
Arise! Cease cringing to your noble's rod,
Demand your heritage, freedon! bestowed by God.
Awake, Awake, Awake!
Throw off your chains, be men.

HALL-SCOTT

HALL-SCOTT MOTORS are offered to reputable aeroplane manufacturers as possessing those refinements in design and construction, together with consistent power delivery, under actual flying conditions, points of merit which are of absolute necessity to permit of meeting Government requirements in flying tests of the aeroplane.

PERFORMANCE

The New York Aero Construction Company's Twin Motored Seaplane has a maximum speed of 85 miles per hour, excelling the estimate by ten miles per hour. Yet it has a slow landing speed of 43 miles per hour, allowing the landings to be made within a much smaller space than is ordinarily the case. But what is even more important in coast defense work is the fact that it has a

FLYING RADIUS OF NINE HOURS

The advantages of a high speed and a wide flying range are obvious. The coasts of the United States are long, and the swifter the machines that guard them, and the longer they can stay in the air, so much better and more easily are the coasts patrolled. The seaplane mentioned in the editorial of the World could, flying at full speed for its seven hours' flying radius, cover 515 miles. The seaplane of the New York Aero Construction Company could cover 680 miles.

820 Sq. Ft. Supporting Surface.
Two 100 H.P. Aeromarine Motors.
Weight 2,700 lbs. Useful load 1,700 lbs.

Maximum speed, 85 Miles per hour.
Minimum speed, 43 Miles per hour.
Flying radius, nine hours.

Designed and constructed throughout under the supervision of Mr. Warren S. Eaton.

BALLOONS OF ANY SIZE AND EVERY TYPE

The Two-Fold Function of Goodyear Cord Tires For Airplanes

An airplane tire has two functions which it must fulfill: it must do its minor duty of bearing the weight of the 'plane in starting, and it must be resilient and strong to fill its major office of defying and absorbing the shocks and strains of landing.

Goodyear Cord Tires for airplanes with their oversize construction and resilient flattening under load accomplish the first even in sand and heavy dust.

Since airplane tires can have no traction purpose, we prefer to attain the end in this way in preference to using roughened or extended treads because the fulfillment of the major function demands the greatest possible strength with the necessary lightness.

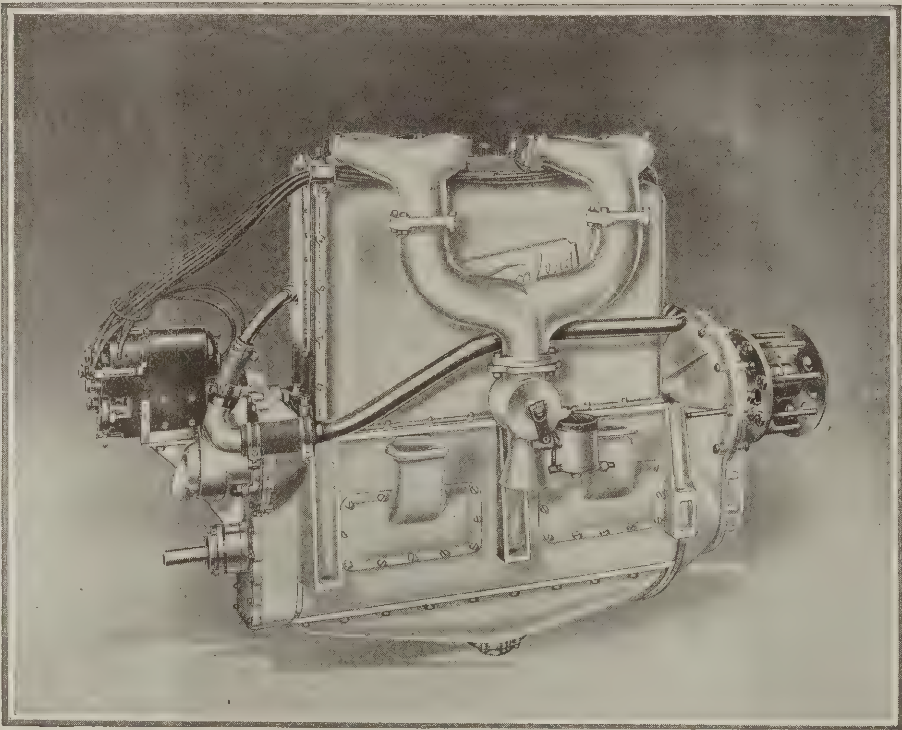
The Goodyear cord construction provides this strength in the fullest of measures.

In the shock of the roughest landing these tires defy the menace of possibly disastrous blow-outs.

They are sure in starting, certain in landing, and light.

The Goodyear Tire & Rubber Co.
Akron, Ohio

GOODYEAR
AKRON



The Four Cylinder, Sixteen Valve

125 Horsepower

Duesenberg Aeroplane Motor

THE Duesenberg Motors hold a dominant position in the field of racing automobiles, where more than 60 per cent of all cars racing on American Motor Speedways are Duesenberg powered. The same condition exists in the motor boat field, where Duesenberg engines have created new records for both speed and dependability. The first mile-a-minute boat in the world—Disturber IV—is powered with a pair of twelve-cylinder, 6¾" x 7½" Duesenbergs. The Displacement Runabout, "Marycel," that made a world's record at the recent Miami Regatta, is powered with an eight cylinder, 6¾" x 7¾" Duesenberg. Many of the Patrol Boats now in the service of the United States Government and also in the service of several of the Allied Governments are Duesenberg powered.

All of which bears out the contention that Duesenberg Design is capable of extreme speed and hitherto unheard of dependability. The four cylinder Duesenberg Aeroplane Motor illustrated above is the adaptation of this design to aeroplane requirements. It has the same famous valve action, the same cylinder construction, the same highly efficient oiling system. In this motor has been produced a power plant weighing 3.5 lbs. per H. P., yet nothing has been sacrificed in rigidity and strength. At its normal speed it develops 1 H. P. for every 3.5 cubic inches piston displacement. It is not a V-type motor, hence offers a minimum of head resistance. Two such motors can be installed side by side and occupy an extremely small space. This motor has two inlet and two exhaust valves per cylinder, which materially adds to its ability to produce tremendous power and to operate at high speeds.

This four cylinder motor is designed for operation with or without a reduction gear. The reduction gear is inbuilt into the motor and consists of heat treated spur gears operating on ball bearings. Reduction ratio, 57:33. This motor is well worthy of your close investigation; it is not experimental, it being simply an adaptation of our well proven principle of design which we have perfected during the past nine years.

Full and complete information will be cheerfully supplied and every courtesy extended to you in carrying out your investigations. Our factory facilities are such that satisfactory deliveries can be made.

Vol. V NEW YORK, MAY 14, 1917 No. 9

SUGGESTION THAT AMERICA SEND 5000 AVIATORS TO EUROPE DISCUSSED IN THE HOUSE OF COMMONS —CORDIALLY ENDORSED BY THE BRITISH AERONAUTICAL PRESS

THE suggestion that America should co-operate with her Allies by concentrating on the construction and commission of a great air service was discussed on the floor of the House of Commons on April 18th, and readers of Aerial Age who have followed the history of aeronautical development in England will appreciate the point of Mr. Lynch's remarks.

The discussion follows:

United States (Air Service)—Mr. Billing (by Private Notice) asked the Chancellor of the Exchequer whether he will appeal to the Government of the United States of America to concentrate immediately on the construction and commission of a great Air Service, and also whether this Government is prepared to supply the American Government with sample machines, engines, drawings and specifications of our latest and most successful types, and to render them every other possible assistance to this end.

Mr. Bonar Law: This subject is already under consideration with the Government of the United States.

Mr. Lynch: Would it not be wise to allow the Government of the United States to decide these questions for themselves on the ground that one of the great assets is an infusion of brains, which are badly needed?

Aeronautical Press Endorses Suggestion

THE proposition to send 5,000 aviators to Europe is spreading. In the current issue of *Flight,* a British aeronautical publication, the part that America may play in the great war, particularly as regards aviation, is described as follows:

"Although the United States is now an Allied nation, possessing almost unlimited potentialities for the assistance of the cause for which we have been fighting for nearly three years, it will still be many months before she can make the full weight of her military power felt on the battlefields of Europe. America is in very much the same position that we were at the beginning of the war. Her regular army is small, maintained only for police purposes, and she is faced with the problem, as we were, of creating an active service army of dimensions worthy of her status as a great power.

"She will accomplish it—as we did—but the process will naturally take time, and it must be many months before the first of the new American armies are ready to take the field against the enemy of civilization. In all probability it will not be before the beginning of 1918 that we shall see them definitely in the field. It is as well that we should realize this, in order that we may be under no misapprehension as to the magnitude of the task that lies before us. But if the full measure of the strength of the United States cannot be put forth at once, there are other things that she can do for the helping of the common cause. These we may depend upon it she will do to the utmost of her power.

"The first manifestation of American good will to help concerns us very closely. It is probable—practically certain—that the first contribution America will make to the fighting strength of the Allies, apart from the services of her magnificent navy, will take the shape of the despatch to Europe of a number of aeroplane squadrons. According to the news that reaches us by cable, a very strong movement is on foot to recruit 5,000 American aviators for immediate service in Europe. Interviewed on the subject by the New York correspondent, Mr. Woodhouse, a governor of the Aero Club of America and of the National Aerial Coast Patrol Commission, said:

"'I have sounded public opinion as to the sending of a large number of aviators to fight with the Allies, and I find general and enthusiastic approval of the plan. There will be no trouble to get 1,000 volunteers to make up American aero squadrons to be sent to Europe. I rather believe there will be many times more applications than are wanted. Students from about twenty universities, including Yale, Harvard, Columbia, Princeton, Cornell, Georgia and the Institute of Technology, are already forming units of the Aerial Coast Patrol, and we have 1,000 applications for aviation training on the file.

"'There will be no trouble whatever in getting the aeroplanes and equipment needed to train and equip these men. It would take about ninety days to establish camps and to give the students their preliminary training, including the theory of flight, aerial gunnery, etc. By that time our American aeroplane factories will be turning out aeroplanes by the hundred. Within six months they will be turning out aeroplanes by thousands. Everything depends upon the prompt action of the Government, reinforced by the general public.

"'With such facilities as we can provide, there is no reason why numerous squadrons, fully trained and completely equipped, should not leave New York within six months, ready for the service training which can only be given on the field of battle.'

"All the news goes to show that the idea is being taken up with the enthusiasm which might be expected in the country which gave practical birth to dynamic flight. While it does not, up to the time of writing, appear to have received the cachet of formal administrative approval, there is little doubt that this will be given, and in the meantime the work of recruiting aviators in anticipation is proceeding apace.

"We could not ask a more acceptable token of the determination of our newest ally to get on with the business of defeating the enemy than the fruition of this idea. Apart from the very great moral effect of seeing the flag of the United States early in the field, the material help that would be afforded to the Allies in the west by a really strong contingent of the American Air Service would be very great. While we have no dearth of recruits for our own flying services, and do not anticipate any, it is nevertheless true that the wastage is appallingly heavy, and will doubtless tend to become even heavier as the campaign approaches its decisive stages. Therefore, we want all we can get, and the American accession to the Allied air strength will be correspondingly welcome."

A CASE FOR THE SPEED SCOUT

The fact that we have in America fighting machines equal in efficiency to the best European machines, is epitomized in the following report of the Advisory Committee on Aeronautics, co-operating with the Commander of the Third Naval District.

Dealing with American speed machines, the report states: *"The fast, single-passenger fighting machine.* It is principally the fact that we have not had machines of this type in use that has created the impression that American machines are not as efficient as European machines. But the first demand for this machine in the United States came only a few months ago, and the first turned out show a speed of 122 miles an hour, with a slow landing speed of 55 miles; a climbing speed of 10,000 feet in ten minutes. And the factor of safety is up to between 5 and 6. Of late the Army and the Navy have both been planning to place orders for machines of this type, and half a dozen manufacturers are prepared to turn them out. The thing to be decided just now is whether the Army and the Navy are willing to adopt the foreign specifications and content themselves with fighting machines that have a factor of safety of two or three and carry two hours' fuel and land at a speed of close to 85 miles an hour. If they will content themselves with this, we feel certain that American manufacturers can turn out fighting aeroplanes that will make a speed of close to 135 miles an hour, which is the very best actual performance obtained abroad, and will have good flying qualities and fast climbing speeds.

"But this low factor of safety and extreme landing speed, while necessary when it actually comes to fighting enemy aviators, can be dispensed with at a cost of only about five to ten miles per hour in speed, so long as our aviators do not have to fight enemy aviators and thereby save considerable injuries to men and machines during the period of necessary training. Our Committee came to this conclusion after watching the succession of breakages of the fast British fighting machine which has been tested at Governor's Island during the past few weeks. This machine was so lightly constructed and landed at such great speed that there was breakage at most of its landings. Finally, two British officers, who brought it over, crated it away. The account of the death of Norman Prince, of the Lafayette Corps, tells that the machine he was flying landed at a speed of close to 100 miles an hour. The new Spad is almost as bad in so far as factor of safety and landing speed are concerned. These are machines to use in battle and American aviators will use them when they get there, but it would be wrong to say that they are better than the American fighting machines being turned out.

"Recently there were printed in New York and Washington criticisms of slowness of American machines, coupled with claims of speed of 150 miles an hour for a newly arrived Vickers battleplane. A few days later those who followed the tests of this 'battleplane' at Governor's Island, witnessed a succession of breakages, due to the light construction ond extreme landing speed of that machine. Again and again it was repaired, only to be damaged again on landing after a flight. The agents who brought it over finally put it away in despair. But even at that no claim was made of the machine having a speed of over 120 miles an hour, because it did not make it.

"This brings us to the claims of excessive speed. Our Committee has found that none of the reports of speeds of upwards of 130 miles an hour have been substantiated. Now, as it has been for the past ten years, we get reports of tremendous speeds attained, but find upon investigation that it is merely hearsay. In our official capacity we have had to consider hundreds of claims of records submitted for homologation, and usually found on actual measurement that the distance covered was much less than the distance claimed. The aviators usually based their figures on railroad distances, but did not allow for the fact that the aeroplane went in straight line, whereas the railroad had detours.

"Miss Ruth Law, on her return from Europe recently, told our Committee that the reports of performances of European machines, particularly the speed, were exaggerated, not intentionally, but as the result of general habit of talking about great speeds. She is only one of many who have brought this to the attention of the Committee."

Seaplanes for Cargo Ships

(Editorial in *N. Y. Sun*)

In two instances during the war submarines have been sunk by explosives dropped from aeroplanes. In September of last year the French submarine Faucault was destroyed by Austrian seaplanes in the Adriatic, and earlier in the war, on January 7, 1915, U-11, an Austrian submarine, was sent to the bottom by an enemy seaplane. These cases are well authenticated. It is well known that the aviator can in certain lights, and particularly in calm weather, detect a submarine beneath the surface of the sea, very much as a fishhawk, flying sometimes at one height and sometimes at another, according to the state of the atmosphere, can see its prey when not exposed.

The success of aviators in attacking submarines has been limited, in fact casual, but only because no systematic seaplane campaign has been made against enemy submarines. There is, of course, a difficulty inherent in expeditions from a land base, for the aviator may go too far out and become a victim of his own daring or carelessness. But this would not be the case if seaplanes operated from the decks of large ships, which is feasible, whether for naval purposes or to protect cargo carriers.

If the decks of big freighters were fitted with runways for the launching of seaplanes, two or more machines could be carried on each voyage. At sea in any but the worst weather, the seaplanes could scout in daylight hours looking for submarines and prepared to attack them with explosives. That they would be a valuable protection to cargo and munition ships will not be disputed. The trial should be made with the least possible delay. We are sure that it would prove a signal success. Thereafter no big freighter would sail without seaplanes and a squad of aviators.

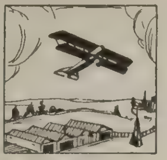
PLANS FOR AVIATION PERSONNEL

THE Chief Signal Officer of the Army, Brig. Gen. George O. Squier, has practically completed the program which it is expected will result in the securing of the hundreds of aviators necessary to bring the section up to the proper strength in the new forces authorized in the Administration Army Bill. Full details of the plan worked out in the office of General Squier cannot yet be made public, but the following outline will indicate the general idea:

Six universities have agreed to detail three or more instructors from their faculties, to be sent to Canada, where they will investigate the scholastic functions of the aviation school at Camp Borden. On their return these instructors will inaugurate a "preliminary course in aernouatics" at their several institutions which will give to the student in the briefest possible time the essential knowledge in that science. From the thousands of applicants for commissions as aviators, officers of the Signal Corps will select 100 from each university. They will be taken into the enlisted reserve of the Signal Corps and ordered to the college for the intensive course of study. Additional aviation schools along the plan of those at Mineola and Memphis will be prepared to give the student the actual flying experience and the finishing touches to his "education." Charles D. Walcott, chairman of the advisory committee on aeronautics of the Council of National Defense, has reported that, as a result of the co-operation of domestic manufacturers, there is absolute assurance that an adequate number of training machines will be available when the students are ready to use them.

The universities already included in the plan are Cornell, Ohio State, Texas State, Illinois State, Massachusetts Institute of Technology and California State. Representatives of these six institutions were in conference with General Squier April 30 and next day orders which will send the investigators to Canada were issued. In the Canadian school one month is allowed for the theoretical subjects and two for the instruction in the "squadrons." It is possible that this time may be cut in the case of the American students, who will be in every sense "picked" men. But should it be deemed best to maintain the Canadian schedule, an output of 200 embryo aviators per month after the end of July seems assured. It is more than likely, however, that the number of institutions will be increased.

The additional aviation schools to be established include one each near Detroit, Mich.; Champlain, Ill.; Indianapolis, Ind.; Dayton, Ohio, and St. Louis, Mo., and the permanent equipping of the schools near Chicago, Ill., and Memphis, Tenn. Major Benjamin D. Foulois, S. C., who accompanied Lieut. Col. J. B. Bennet to Canada last week, has been ordered to make a thorough inspection of the grounds available at each of these places and to report the result as soon as possible. The ten aviation fields between Columbus and Dayton, Ohio, equipped and owned by a prominent aircraft company in the latter city, may be used by the students at Ohio State University. As a general thing it is intended that the prospective aviators shall only receive at the aviation schools instruction in mechanics, physics and other theoretical subjects necessary in aeronautics and military drill.



THE NEWS OF THE WEEK

Tentative Plan by War College

The tentative plan drawn up by the Army War College and submitted to the General Staff, dealing with the composition of the army to be developed from the first 500,000 men called by the President under the selective draft provisions of the new Army Bill, provides for eight aero squadrons and eight balloon companies. The plan is as follows:

DIVISIONS

16 Infantry Divisions; each 913 officers and 27,243 men.
16 Divisional Hospitals; each 24 officers and 222 men.
64 Camp Infirmaries; each .... officers and 2 men.
2 Cavalry Divisions; each 607 officers and 16,021 men.
2 Divisional Hospitals; each 24 officers and 238 men.
6 Camp Infirmaries; each .... officers and 2 men.
Medical Corps (total) 288 officers and 1,000 men.
Coast Art. Corps (total) 666 officers and 20,000 men.

ARMY CORPS TROOPS

16 Brigades F. A. (heavy); each 48 officers and 1,319 men.
8 Aero Squadrons; each 10 officers and 154 men.
8 Balloon Companies; each 19 officers and 154 men.
10 Field Hospitals; each 6 officers and 73 men.
10 Ambulance Companies; each 5 officers and 150 men.
22 Field Bakeries; each 1 officer and 67 men.
6 Telephone Battalions; each 10 officers and 215 men.
16 Pack Companies; each .... officers and 14 men.
6 Ammunition trains; each 4 officers and 852 men.
6 Supply trains; each 2 officers and 426 men.
Grand total, all units, 185,338 officers; 528,659 men.

The officers for this force will be drawn from the Regular Army and the National Guard the Officers' Reserve Corps and "the country at large." The War College recommended that 200,000 men be withdrawn from the army and guard (when both are recruited to full authorized strength) for appointment as company officers and non-commissioned officers in the new army. The College advised against any estimate which would give less than 150,000 men from this source.

It is the specific purpose of the War Department that each regiment in the new forces shall be commanded by an officer from the regular establishment, and that at least one of his majors and all of the staff officers (adjutant, ordinance, supply officers, etc.) shall be experienced men from the regular army.

Steam Aeroplanes Predicted

Detroit.—Abner Doble, vice-president of the General Engineering Company, believes that steam as a motive power for aeroplanes may be used in the near future. The power plant of the Doble steam car which is manufactured by the General Engineering Company develops one horsepower per ten pounds weight, which is a better ratio, according to Mr. Doble, than that of a complete power plant of a gas car and when used in an aeroplane is not encumbered with clutch, change-speed transmission, and starting apparatus, and the ratio of weight to power is greatly reduced. Mr. Doble is experimenting on his power plant for aerial purposes in an endeavor to reduce the weight, and expects to lighten the boiler and engine by careful adaptation of design and the use of special materials. The electrical apparatus may be virtually eliminated by taking advantage of the draft supplied by the propeller and the velocity of the plane. Water supply can be greatly reduced for aviation work, while the weight of the lubricating oil supply would be negligible. Mr. Doble pointed out that the advantages of a steam power plant lie in longer continuous service, tremendous reserve power, and rapid acceleration.

French Airmen Send Greetings to America

The French aeronautical organization, the League Aerienne Française, of Paris, has cabled the Aero Club of America its felicitations and fraternal greetings to the aviators of America, who will soon be with them in the great world struggle. The league, which was founded to promote the cause of military aviation in France, counts among its members some of the foremost men of France.

The cablegram reads:—"The Executive Committee of the League Aerienne Française, founded in October, 1915, to attain the supremacy in military aviation, sends its felicitations and fraternal greetings to the areo clubs of the United States and to the champions of the Grand Republic. We greet the American aviators, who now enter into battle and will alight upon the soil of France, and all those who will come to fight with the allies for civilization and liberty."

Oldfield Motors to Build Aero Engines in Duluth

Duluth, Minn.—A new industry to manufacture aeroplane engines will be established here and will be known as the Oldfield Motors Corp. The aeroplane engine which will be made by this company will be 125 h.p. The company has taken over the old plant here, comprising several buildings, and the main building is 140 by 160 ft. The president of the company is Lee W. Oldfield, and associated with him are John B. Cooper, John P. Ernster, Harry M. Giles and Alfred Kreig.

Wardrop Speaks in Albany

That the engineers and students of modern military efficiency in the Albany district are cordially interested in the subject of aviation was demonstrated on May 4th, when G. Douglas Wardrop, editor of AERIAL AGE, delivered an address at the University Club before a large audience. A number of the auditors made application for enlistment in the Aerial Reserve Corps as a result of the enthusiasm created concerning our air services.

Record Number of Pilots' Certificates Granted

A record number of aviation pilot certificates were granted by the Executive Committee of the Aero Club of America last week. Sixteen men received their certificates, one of whom also received his expert pilot certificate. This brings the total of licensed pilots of the Aero Club of America up to 860, which includes 66 hydroaeroplane certificates, 710 land certificates and 84 expert certificates.

Those obtaining their certificates were: Carl W. Connell, Mayo H. Boulware, Michael Brown, Joseph Bennett, Roland Rohlfs, 1st Lt. Michael F. Davis, U. S. A.; 1st Lieut. James R. Alfonte, U. S. A.; 1st Lieut. Adlai H. Gilkeson, U. S. A.; 1st Lieut. Patrick Frissell, U. S. A.; 1st Lieut. Arnold N. Krogstad, U. S. A.; 1st Lieut. Whitten J. East, U. S. A.; Captain John H. Reynolds, U. S. A.; 1st Lieut. H. M. Brown, U. S. A.; Charles T. Holloway, Harry Wagner, Edward P. Larrabee.

The Expert Certificate was granted to Carl W. Connell, No. 84.

S. A. E. to Meet on June 25-26

Washington.—The summer meeting of the Society of Automobile Engineers scheduled to be held in this city on Monday, June 25, will be a two-day session, instead of a one-day session as previously announced. Monday, June 25, and Tuesday, June 26, will be devoted to the work. Sessions will be held in the Auditorium of the Bureau of Standards, which is some distance out from the center of the city. This change in arrangements followed a two-day conference of several of the members of the council of the society who have been here for two days arranging for the summer meeting and also taking up matters of closer co-operation of the society with the Government.

STANDARDS MEETING JUNE 25

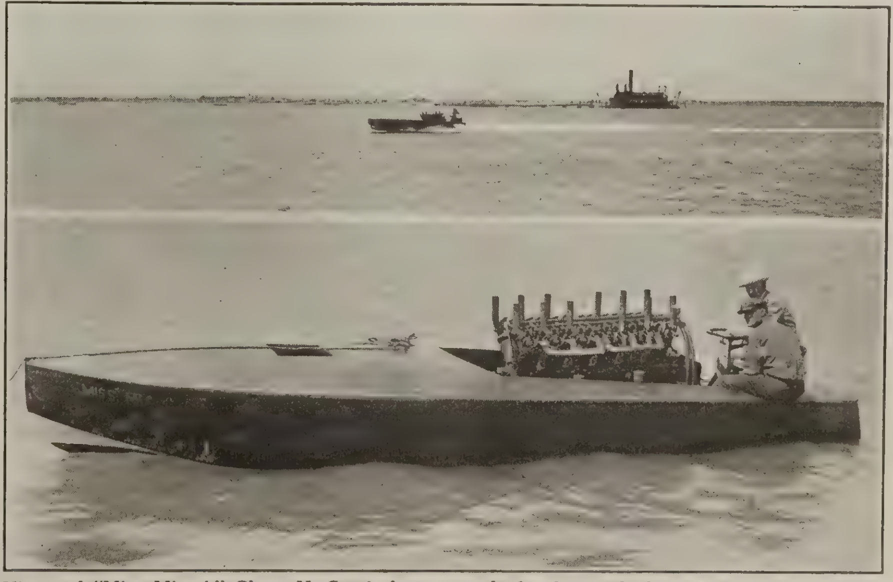
A definite program for the two-day meeting has not been exactly determined upon, but a rough draft shows that the work of Monday, June 25, will be entirely given over to the standards committee, which will meet at 10 A. M. at the Bureau of Standards and continue in session for the remainder of the day.

The evening will be given over to examination of the equipment of the Bureau of Standards and perhaps some special demonstrations arranged for the engineers.

GENERAL MEETING JUNE 26

Tuesday, June 26, will be for the entire membership of the society, the program consisting of a business meeting with president's address and various reports in the forenoon, followed by a professional session in the afternoon, and an informal dinner in the evening. The afternoon session will have approximately three or four papers of a practical nature dealing largely with the work of the different activities of the society in relation to the Government. It is hoped that one of the foreign aviation engineers will present a paper on this subject.

Many members of the society are making headquarters in Washington at present and the New Willard Hotel here recalls a New York hotel at show week, so many of the automobile, aeroplane and tractor people are on hand. Closely associated with Government co-operation are many members of the S. A. E. W. H. Van Dervoort, past-president, has a permanent office in the Munsey Building in connection with his work on standardization of munitions; S. D. Waldon, formerly of Packard and Cadillac, has an office in the same building and is working on matters of aeroplane organization and problems connected with increased production; K. W. Zimmerschied, former chairman of the Standards Committee, is lending aid in a general way and expects to make headquarters here for some time; Charles B. King, one of the pioneers in the automobile industry, has been working with the Government for many months; Henry Souther, former president of the S. A. E., has been connected with the aeroplane department in an engineering capacity for nearly a year. Howard E. Coffin, also past-president of the society, has been giving all of his time to defense work for practically a year. President George W. Dunham, of the S. A. E., has recently been given an appointment on the bureau for the development of motor apparatus for moving field artillery. Roderick W. Stephens, president of the Motor Truck Club of America, is devoting all of his time to recruiting truck drivers.



Views of "Miss Miami," Glenn H. Curtiss' one-step hydroplane, which recently made sixty-six miles an hour in official trials at Miami, Florida, breaking the world's record

Lieut. E. R. Kenneson, who is instructing the members of the Princeton Aviation Corps.

Steinmetz Lectures to Engineers

Mr. Joseph A. Steinmetz, of Philadelphia, President of the Aero Club of Pennsylvania, member of the American Society of Automotive Engineers, and of the National Association of Engine and Boat Manufacturers and various other scientific societies, delivered a lecture before the Brooklyn Engineers' Club on the evening of Thursday, May 3, 1917, on "Aerial Warfare and Some Devices, Terrestrial and Submarine." The lecture was illustrated, and aroused tremendous interest.

Army and Navy Orders

Detailed to 1st Aero Squadron

The following officers are relieved from duty at Signal Corps Aviation School, San Diego, and will proceed to Columbus, N. M., and report to C. O., 1st Aero Squadron, S. C., for duty: Capt. William A. Robertson, junior military aviator, S. C.; Capt. Seth W. Cook, Cav., D. O. L.; Capt. James F. Byrom, junior military aviator, S. C.; Capt. Joseph T. McNarney, junior military aviator, S. C.; 1st Lieuts. Ralph P. Cousins, Cav.; Melchoir McE. Eberts, Inf.; William O. Ryan, Cav.; Charles C. Benedict, Inf.; Lawrence S. Churchill, Inf., D. O. L.; George E. Stratemeyer, Inf.; George W. Krapf, Inf., D. O. L., and Harold M. Clark, Cav., D. O. L. (April 30, War D.)

Sergt. 1st Class Edgar C. Athey, S. C., Aviation School, Memphis, Tenn., is transferred as private to Coast Artillery Corps and to the Coast Defenses of Portland. (April 26, War D.)

Sergt. 1st Class Arthur J. Ohm, S. C., from further duty at Columbus, N. M., to Signal Corps Aviation School, Memphis, Tenn., for duty. (April 27, War D.)

Capt. Howard F. Wehrle, Aviation Section, S. O. R. C., to active duty at Aviation School, Mineola, Long Island, N. Y. (April 27, War D.)

First Lieut. William P. Willetts, Aviation Section, S. O. R. C., to active duty at Mineola, Long Island, N. Y. (April 27, War D.)

First Lieut. Frank W. Goodale, Aviation Section, S. O. R. C., to active duty at Fort Omaha, Neb., Balloon School. (April 25, War D.)

Under the provisions of the National Defense Act, approved June 3, 1916, the organizations hereinafter designated will be organized and stationed as follows:

Second Aero Squadron, Signal Corps, Philippine Islands.

Fourth Aero Squadron, Signal Corps, near San Antonio, Texas.

Fifth Aero Squadron, Signal Corps, near San Antonio, Texas.

Sixth Aero Squadron, Signal Corps, Hawaiian Islands.

Seventh Aero Squadron, Signal Corps, Canal Zone.

The commanding generals of departments to which these units are assigned will complete these organizations by the assignment of such officers and enlisted men of the Aviation Section now in or to be sent to their departments, and by the transfer or enlistment of qualified enlisted men from other branches of the service, or from civil life.

Boards Appointed

A board to consist of Capt. Lewis E. Goodier, jr., retired, and 1st Lieut. John P. Gallagher, M. O. R. C., at Essington, Pa., for examination of candidates for appointment as officers in the Aviation Section, Signal Officers' Reserve Corps. (April 30, War D.)

A board to consist of Capt. Roy S. Brown, junior military aviator, S. C., and 1st Lieut. George W. Woodnick, M. O. R. C., at Chicago, Ill., for examining applicants for appointment as officers in the Aviation Section, Signal Officers' Reserve Corps. (April 28, War D.)

The Southern Department has been authorized to begin the establishment of a new aviation field. Options have been obtained on 1,000 acres of land six miles south of San Antonio, Texas. General Perishing also has been ordered to organize two more aero squadrons, each to have 150 officers and men and twelve aeroplanes.

Special Regulations No. 50, Aviation Section, Signal Corps of the Army, governing its organization, has been issued by the War Department. It is dated April 9, 1917, and relates to personnel and duty, schools, requirements for service in Aviation Section, Signal Officers' Reserve Corps, and Enlisted Signal Reserve Corps, aviation sections, civilian aeronautical schools, etc.

Bureau of Standards Offers Facilities for Summer Session of S. A. E.

Washington.—The Bureau of Standards, under the direction of Dr. Stratton, has advised that its auditorium and other necessary parts of the bureau will be at the disposal of the Society of Automotive Engineers for its Summer Meeting, Monday and Tuesday, June 25 and 26. The bureau has been co-operating with the society in many ways connected with standardization work and this courtesy is another example of how desirous the Government is to work with the engineers.

The meeting on Monday, June 25, will be given over entirely to the work of the Standards Committee.

Tuesday, June 26, will be occupied by the general work of the society, including a business meeting in the morning, receiving of reports, and professional papers in the afternoon.

F. E. Moskovics has accepted the chairmanship of the committee for the informal dinner Tuesday evening, June 26. The exact place at which this dinner will be held has not yet been decided upon. Mr. Moskovics is in the city this week arranging for the dinner and adding to his committee to handle this work.

New York Meeting of Aeronautic Division S. A. E.

A meeting of the Aeronautic Division was held April 20 in New York, those present being Chairman Charles M. Manly, H. M. Crane, F. S. Duesenberg, Spencer Heath, C. B. King and J. G. Vincent, General Manager Coker F. Clarkson and Recorder A. C. Woodbury. The visitors present were: Frank W. Caldwell, Aviation Section, Signal Corps, and M. W. Hanks, of the Westinghouse Electric & Manufacturing Co.

The Division voted to report for adoption the Deperdussin (Dep) and stick controls for aeroplanes. Sketches to indicate the effects of the various control movements will be incorporated in the report.

It was decided to recommend that clincher rims, conforming to the standards of the Clincher Automobile Tire Manufacturers' Association, should be specified for aeroplanes. The rim sizes to be recommended are 24 by 3½, 28 by 4, and 32 by 4½ in. Tires of corresponding sizes are to be used with these rims, as are also oversize tires as follows: 25 by 4, 29 by 4½, and 33 by 5 in.

Considerable discussion was had regarding the standardization of hubs and spokes. It was thought that three sizes of hubs, 6, 7 and 8 in. long, would be sufficient, but it was finally decided to consider the subject again at the next meeting of the Division. Proposals were also submitted for standardizing two sizes of wire spokes, the large size having the butt end bent to an angle of 41½ deg. and the small size an end bent to an angle of 90 deg.

It was voted to recommend the method of fastening ends of hard wires corresponding to the present British standard. This consists of an oval coil of wire, through which the hard wire is slipped, bent in the form of a loop, inserted again and the end bent over against the coil, the hole then being soldered.

Dimensions were submitted for flexible splices for cables from 3/32 to 7/32 in. diameter. It was voted that these splices be proposed for standardization. Dimensions were also submitted for galvanized non-flexible cable ends for cables of from 1/16 to ¼ in. diameters. These splices will probably be recommended for adoption.

A set of thimbles for wire ends has been approved for submission to the Standards Committee. These apply to wire of from 1/16 to ⅜ in. diameter.

The subject of turnbuckles was considered, and it was decided to recommend for immediate adoption short and long turnbuckles, the barrels of which are 2 and 4 in. long, respectively.

It was decided to approve the following pipeline markings for presentation to the Standards Committee: Gasoline pipe lines are to be marked with red stripes ½ in. wide, painted around the pipes 24 in. apart. Oil lines are to be marked with white stripes ½ in. wide, painted around the pipes 24 in. apart.

The following recommendation was approved with regard to specifications for thickness of metal:

"Sheet metal is to be specified by thickness in decimal fractions of an inch. Rods, wires and cables are to be specified by diameter in decimal fractions of an inch. Tubes are to be specified by outside diameter in inches or fractions and thickness of wall in decimal fractions of an inch."

It was voted to recommend the following engine-support dimensions for adoption, omitting all reference to sizes of bolts:

Distance between timbers..	12	14	16
Width of bed timbers.....	2	2¼	2½
Distance between centers of bolts	14	16¼	18½

A resolution was passed that in view of the necessity of arriving at standards that will mean the least possible delay in the production of aeroplane parts, the Division recommends the use of the English system of measurement, except in isolated cases, such as spark-plug threads, for which the metric system is desirable in order to effect interchangeability with some well-established standard.

It was decided to approve a metric spark-plug with an 18-mm. thread and 1½-mm. pitch. The form of the thread is to be the International metric standard. The distance from the gasket shoulder to the end of the shell is to be ⅝ in. The hexagon is to be 1 in. across the flats.

The following list of existing S. A. E. Standards was approved for aeronautic practice—steel specifications, heat treatments, test specimens, ball bearing sizes, throttle levers, magneto dimensions and cotter pin sizes.

Other matters approved for submission to the Standards Committee are a design of tachometer shaft-end and a safety belt adopted by the War Department.

Universities to Be Training Schools

Washington, D. C.—Six universities have been designated by the War Department as training schools for prospective army aviators, who will have two or three months' instruction in physics, mechanics and military drill, beginning in about six weeks. The schools are Cornell, Illinois, Ohio, California and Texas Universities and the Massachusetts Institute of Technology.

Some of the six thousand applicants for the army aviation corps will be selected for assignments to the university after preliminary physical and mental examinations. Meanwhile each of the universities will send three members of its faculty to study practical aviation problems at the Canadian training school, connected with the University of Toronto. Heads of the institutions meeting with Brigadier-General George O. Squier, chief of the army aviation service, agreed to these arrangements.

The War Department intends to send practical aviators to each training school to assist the three faculty members in directing the courses, although the present intention is not to use the university campuses as aviation fields. Actual flying training will be given to the students at the army's aviation camps. All the schools chosen already have military instruction.

Other schools probably will be chosen later for similar training centers.

Arrangements for the university courses were made through the Aeronautics Committee of the Council of National Defence, with which aeroplane manufacturers are co-operating to supply machines ordered by the air department.

A remarkable picture of a Curtiss J. N. tractor taken from F. C. G. Eden's flying boat at Jacksonville, Florida. The two machines were instrumental in discovering a forest fire, the smoke of which can be clearly seen in the lower left hand corner of the illustration.

REGULATIONS GOVERNING THE ORGANIZATION OF THE AVIATION SECTION, SIGNAL CORPS

SECTION I.

PERSONNEL AND DUTY.

1. Personnel.—The aeronautical personnel of the aviation section of Signal Corps will consist of officers and enlisted men of the Regular Army, of reserve officers and enlisted men of the Reserve Corps, of officers and enlisted men of the National Guard mustered into the service of the United States, and of civilians employed by the aviation section of the Signal Corps.

2. Division of duty.—The central office will provide for four divisions of duty:

First. The provision of material to be effected by the central office through its technical departments.

Second. A system of training personnel, to be decentralized but to remain under the general jurisdiction of the War Department similarly to other educational institutions and service schools of the Government.

Third. The establishment, organization, and equipment of tactical units at points to be designated by the War Department.

Fourth. The selection, purchase, and rental of sites for aeronautical purposes.

SECTION II.

SCHOOLS.

Par.
Classes of schools 3
Training 4
Military departments 5
Personnel 6

3. Classes of schools.—Aeronautical schools are divided into three general classes: (*a*) The United States Army aviation schools, (*b*) the United States Army balloon schools, (*c*) civilian schools (aviation or balloon), conducted by manufacturers or others for preliminary training.

4. Training.—The personnel and courses of technical instruction at United States aviation and balloon schools will be in accordance with instructions from the War Department.

It is intended that personnel for all formations, except those of the Regular Army, will obtain their preliminary instruction at civilian aviation or balloon schools, after which they may finish the course at the corresponding United States Army schools and obtain their military ratings.

5. Military departments.—Each department will have an aeronautical officer, to be designated as such, on the staff of the department commander.

Within the department, the aeronautical officer, under the department commander, will be charged with general control of all officers, enlisted men, and civilian employees of the aviation section, Signal Corps, and of all aeronautical schools except in matters relating to changes in courses of technical instruction and such control by the War Department of personnel at such schools as may be necessary to carry out properly the prescribed courses of instruction; with keeping the records of personnel in the Signal Officers' Reserve and Enlisted Reserve Corps, of the aviation section, Signal Corps; with instruction and equipment of all tactical units of heavier-than-air and lighter-than-air craft; with preparation of requisitions for proper supply of new air units both in the Regular Army and the reserve of the Regular Army; with plans for the creation of new air units in the Regular Army and reserve and with all other matters affecting the aeronautical service. General supply depots and experimental stations so designated in orders of War Department and matters relating to changes in personnel and courses of technical instruction at United States Army aviation and balloon schools within the department are excepted from control and supervision of the aeronautical officer.

6. Personnel.—For the aviation section, Signal Corps, will be as now prescribed by law and Army Regulations.

For the aviation section, Signal Officers' Reserve Corps, under section 37, national defense act, will be as prescribed in Special Regulations No. 43, War Department, 1917, as per Section III hereof; and for the Enlisted Reserve Corps, aviation section, Signal Corps, under section 55, national defense act, as prescribed in Section IV hereof.

Requirements for civilian aeronautical schools are contained in Section V.

The method of detailing officers and men of the National Guard, both in and out of the Federal service, for duty at aviation schools under section 99, national defense act, is set forth in Section VI.

SECTION III.

REQUIREMENTS FOR SERVICE IN THE AVIATION SECTION, SIGNAL OFFICERS' RESERVE CORPS.

7. Number and grades of officers.—The section may consist of 296 officers. The grades in said section shall be in the same proportion as those obtaining in the aviation section, Signal Corps, United States Army, to include the grade of major. Unless otherwise authorized by proper authority, all successful applicants for commissions in the aviation section, Signal Officers' Reserve Corps, will be commissioned in the grade of first lieutenant.

8. Letter of application for examination.—Any male citizen of the United States, not under 21 nor over 30 years of age, desiring a commission in the aviation section, Signal Officers' Reserve Corps, will submit a letter in the prescribed form to The Adjutant General, United States Army. The maximum age limit in special instances may be waived upon recommendation of the officer in charge of the aviation section, Signal Corps.

Form of letter of application for examination for commission in Officers' Reserve Corps.

[Under section 37, act of June 3, 1916.]

——— ———,
——— ———, 19—.

[1]To ——— ———
——— ———
——— ———

Sir: I have the honor to apply for examination for a commission as [2]——— aviation section, in the Signal Officers' Reserve Corps, organized under the authority of Congress.

I have served ——— years in [3]———.

I have pursued a regular course of instruction for ——— years in [4]———.

I graduated in the year ——— from [5] ———, after having creditably pursued the course of military instruction therein provided.

I was born ———, [1]———, at ———, and am [6]——— a citizen of the United States. Age ———. Color ———. Height ———. Weight ———.

My business is ———.

My experience is ———.

I inclose letters of recommendation and addresses of three citizens who know me as follows: ——— ———.

Respectfully,
——— ———.

Permanent post office address ———.

The correctness of the statements above made was sworn to and subscribed before me——— ———, 19—.

[7] ——— ———.
——— ———.

---

Thorne Donnelley, of Lake Forest, Ill., one of the patriotic young sportsmen who have given up their business to further the interest of the country's aerial preparedness.

THE GALLAUDET NAVY SEAPLANE

IN the Gallaudet Navy Seaplane the structural advantages of the tractor type are combined with the advantageous seating of the occupants that are found in pusher machines. Pilot and passenger, being forward of the planes and propeller, have a wide and unobstructed range of vision which is so necessary in observation flights and in making successful landings.

The company recently delivered to the Navy Department a seaplane equipped with the new Gallaudet patented drive. The propeller efficiency, due to Mr. Gallaudet's patented construction, is 83% against the 75% maximum efficiency usually hoped for in propellers in the past. This type of construction eliminates a great deal of the head resistance, reduces weight, and permits the one four-bladed propeller revolving on a drum around the fuselage to be driven by either or both motors set inside the body of the machine and geared to the propeller shaft.

Another feature that makes for speed is that the centers of thrust and resistance are coincident.

The natural stability found in Gallaudet aeroplanes, produced by the pronounced sweepback and stagger and careful distribution of weights and areas is even more evident in the navy seaplane. Streamlining has cut down head resistance to a minimum and in official flights for the Navy Department, a speed of 92 miles an hour was developed, although the high speed specified by the Department was 88 miles an hour.

With a total flying weight of 4,600 lbs., the cruising radius is 1,000 miles; in straight-away flights, 500 miles and return.

General Dimensions

Span, upper plane	48′-0″
Span, lower plane	48′-0″
Chord	7′-0″
Total lifting area	658 sq. ft.
Gap	7′-7″
Overall length	33′-0″
Net weight, unloaded	3,600 lbs.
Useful load	1,000 lbs.
Speed range	92-45 m.p.h.
Motors, Duesenberg (2) each	150 H.P.

Planes

For the sake of clearness in the accompanying line drawing, the wiring of the cellule and main float has been omitted.

Planes have no dihedral. Sweepback, 8° 30 minutes. Upper plane staggered 77° or 1′-9″ forward of the lower. Planes set at an incidence of 7 inches. Ends of planes are raked at an angle of 22°.

The planes are in six sections. Central sections, above and below the fuselage, 2′-4¼″ wide. Each central section has an area of 23.48 sq. ft. Each of the four outer sections has an area of 138.76 sq. ft.

Ailerons on upper and lower planes each have an area of 13.88 sq. ft.

Center panel struts are centered 2′-4¼″ apart. The center interplane struts are spaced 8′-7.83″ from these. From the center interplane struts the outer struts are spaced 8′-6.308″. This leaves an overhang of 5′-2″ from center line of outer strut to the outer tip of aileron. From forward to rear main wing beam, struts are located 4′-4″ apart.

Fuselage

Overall length 29′-6″. Fuselage is built up of mahogany veneer. Maximum width and depth between the central wing panels, 3′-6″. Sides are flat, with top and bottom rounded off.

The leading edge of the propeller is located 16′-0″ from the nose of the fuselage. Aft of the propeller, the body tapers to a vertical chisel edge, to which the rudder is attached.

The observer and pilot are located in separate cockpits in the nose of the fuselage.

Tail Group

The horizontal stabilizer is divided, one section at either side of fuselage. It is fixed at a lifting or positive angle of 3″ in its length of 6′-0″. Along the rear beam ot the stabilizer, the distance from tip to tip is 10′-4″. The rear beam is situated at the center line of the fuselage, which is also the center line of propeller thrust. Area at either side of fuselage, 15.17 sq. ft. or a total area of 30.34 sq. ft.

Each of the two elevators has an area of 11.5 sq. ft. They measure 12′-0″ from tip to tip and are 2′-6″ wide. Attachment to the stabilizer is by four hinges each.

There is no vertical fin or stabilizer. The rudder is of the balanced type. Maximum width, 3′-6″. Maximum height, 5′-0″. Area, 12.5 sq. ft. The rudder area is equally disposed above and below the fuselage.

Floats

Floats of mahogany. Main float is 25′-0″ long. Maximum beam, 3′-6″. Maximum depth at the step, 2′-6″. Attachment is made to the fuselage by a pair of struts at the forward end and a single strut at the rear end. Attachment to the lower plane is by two pairs of short struts.

The float projects 8′-0″ in front of the upper plane, or 1′-0″ forward of the fuselage nose. The step occurs 13′-6″ from the front of the float. Two air vents are run from back of step to the deck of the float. The bottom is the V type, and the top has a turtle back deck. A rudder for steering on the water is hinged to the float extremity.

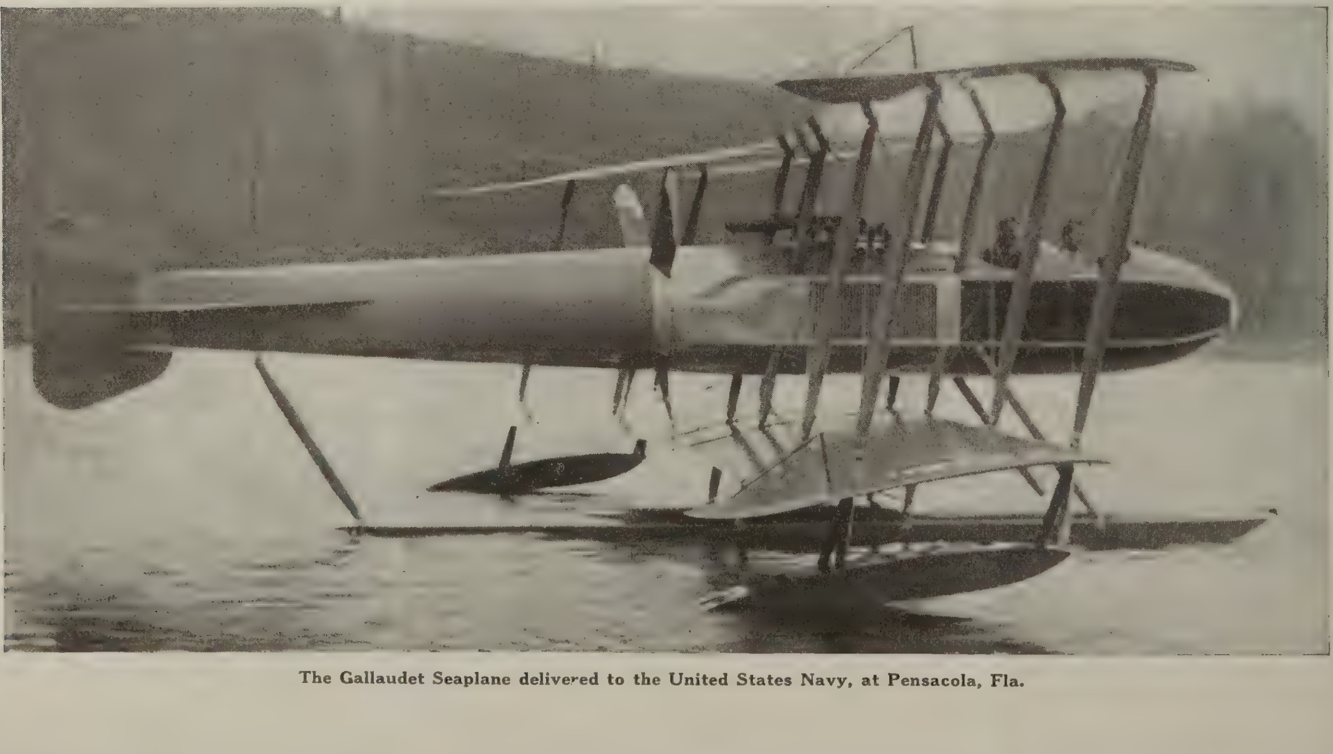
The center line of buoyancy is located at a point 1′-3″ forward of the step. The center line of lift of the machine occurs 1″ back of the buoyancy line. The water line indicated on the drawing is for a load of 3,573 lbs.

Wing tip floats are 1′-3″ wide. Top and bottom flat and sides of streamline contour.

Motor Group

Two Duesenberg 4-cylinder vertical motors are installed in the fuselage. The bore and stroke is 4¾″ x 7″, and it develops 150 h.p. at 2,100 r.p.m. Weight with reduction gear, 509 lbs. A complete description of the Duesenberg motor appeared in the April 23d issue of AERIAL AGE.

The propeller is four-bladed, 9′-6″ in diameter. The blades are attached to a metal ring which encircles the fuselage at a point 16′-0″ from the nose. Spur gears connect the motors to the propeller ring. Radiators built in at either side of the body.



The Gallaudet Seaplane delivered to the United States Navy, at Pensacola, Fla.

EXPERIMENTAL RESEARCHES ON THE RESISTANCE OF AIR

By L. MARCHIS

CHAPTER I

CLASSIFICATION OF EXPERIMENTAL METHODS

1. Reactions Exerted by the Air on a Body in Relative Movement with It

When a body is in movement relative to the air with which it is surrounded, it is subject to a system of forces to which is given the name of "reactions exerted on the body by the air." These reactions are variable, especially as regards (1) the form of the body, (2) the position which it occupies in relation to the surrounding medium, (3) the various circumstances of its movement (time elapsed from origin of movement to present moment—velocity relative to the air), and, finally, (4) the mass of the fluid which surrounds the body in movement.

We shall not develop in detail the difficulties presented by each of these problems, of which certain have received only very imperfect solutions.

We shall, in what follows, consider only the case of a body surrounded completely by a great mass of air, relative to which it has a movement, established a long time previously, and of which the velocity and direction are constant and readily determined.

The reactions exerted by the air on the body in movement relative to it are reduced to a force and a couple. We shall assume that the body under experiment possesses, at the least, a plane of symmetry, thus eliminating the couple from the reactions of the air and reducing them to a single force, to which we shall give the name of "resistance of the air on the body in movement relative to it."

When we consider the movement of the body relative to the air which surrounds it, we have not only in view a movement of translation, but also a movement of simple rotation and likewise a movement of rotation combined with a movement of translation. In other words, we shall study here the problem of the propeller as well as that of the wings of an airplane.

2. Manner of Producing the Movement of a Body Relative to the Air Which Surrounds It—Body Movable

Various experimental methods may be utilized in order to produce the moveemnt of a body in reference to free air.

In an indefinite mass of air, at rest as a whole, the following types of movement may be given to the body:

(*a*) A movement of rectilinear translation;

(*b*) A movement of rotation about the axis of a mechanism;

(*c*) An oscillating movement, as in the case of a pendulum.

The methods by means of some form of mechanism or by means of a pendulum have been but little employed in France and we shall omit special reference to them.

The method employing the motion of translation may be applied in two forms:

(1) The body is allowed to fall freely in air, as calm as possible.

(2) The body is carried on some form of car which is moved in calm air.

In France the method of free fall has given rise to important investigations made by MM. Cailletet and Colardeau and especially by M. G. Eiffel.

The method by means of a car is now utilized by the Aerodynamic Institute of Saint-Cyr, at the laboratory of military aerostation of Chalais-Meudon, and also by M. the Duke of Guiche. At Saint-Cyr and at Chalais-Meudon, the car is composed of a carriage moving on rails. M. de Guiche employs an automobile as a carrier.

A variant of the method of the car has been installed at the laboratory of military aviation at Vincennes. On a stretched cable a little hanging car rolls, carrying, attached below it, the objects under test with the necessary instruments.

The dimensions of the bodies on which the experiments are carried out may be of the order of those which are utilized in aviation itself. In other words, it is possible to operate upon equipment as used in actual aviation, or at least presenting dimensions differing but little from those used in practice.

From this point of view the method by displacement through the air opens up a field of investigation more extended than the method in which an artificial current of air is employed.

3. Manner of Producing the Movement of a Body Relative to the Air Which Surrounds It—Artificial Current of Air

It is possible, in fact, to realize in an entirely different manner the relative movement of a body through the air.

Instead of moving the body under test, a fixed position is given to such body placed in an artificial current of air.

The body may then be disposed in the free air in front of the orifice through which the air enters under regulation by means of suitable devices. This method has been employed by M. Rateau.

The body under investigation may also be placed in an inclosure or integral part of the apparatus for the regulation of the current of air. It is placed, for example, in a part of a large cylindrical pipe which receives a current of air produced by a fan and of which the velocity, at a certain distance from the walls, has been rendered sensibly parallel to the pipe.

This method, furthermore, may be subject to certain variations:

(*a*) The body under investigation alone is placed in the inclosure in the interior of which the artificial current of air is produced. The apparatus for measuring the reactions of the air are on the exterior of this enclosure, their connection with the interior being made through the solid wall which limits the conduit.

This method is known under the name of the "tunnel method." It has not been largely employed in France. There exists at the present time at the Aerodynamic Institute of Saint-Cyr a tunnel of which the practical use has been interrupted by the present war.

(*b*) The apparatus employed for determining the circulation of the air is enlarged into a chamber of suitable size, traversed between two of its parallel walls by a cylinder of moving air. On the outside of the latter and within the chamber are located the experimenters with the necessary measuring apparatus.

We propose to call this the "Eiffel method."

In France this method has given very complete results. It is for us the characteristic method in connection with the use of an artificial current of air.

From the point of view of the convenience of carrying on the experiments, especially in large numbers, the last method is superior to the method by displacement in free air. The latter demands, in fact, that the external air shall be as calm as possible. This condition can only be realized on certain days and then only for certain hours of a given day. If along the right-line path of the body under investigation the wind should have everywhere the same intensity and the same direction, due allowance might be made for its existence.

But many investigations, notably those of M. Maurain at the Aerotechnic Institute of Saint-Cyr, show that at any given point in the air the wind is frequently subject to continued changes in direction and intensity.

But even if it allows the experimenter to regulate the conditions of any one investigation, the method by the use of the artificial current of air can only be applied to models reduced in size in comparison with actual practice in aviation. We shall see later the reason for this limitation.

One question immediately presents itself: How may the results obtained in the study of models be transformed in order to furnish information applicable to apparatus of full size? What is the law of similitude which makes possible the transformation of an investigation on a small scale to corresponding phenomena on a large scale. This is the matter which we shall especially develop at a later point.

A further question presents itself: Do the methods mentioned above, namely, the displacement of the body under investigation and the method by the artificial current of air, lead to the same results? M. Eiffel maintains the affirmative, relying upon the fundamental principle of relative movement. M. de Guiche maintains the negative, arguing that the tunnel method does not realize fully the conditions which permit the application of such a principle.

We shall return to this question at a later point, in connection with the comparison of the results obtained by these two experimenters.

4. Studies of Aeroplanes in Free Flight

The methods which we have just considered require that the body under investigation be connected in a fixed manner with a support. The latter has, under good conditions, its dimensions reduced as much as possible. It is also removed as far as possible from the body under investigation, so that its presence will produce the minimum of disturbance. It is none the less true, however, that the airplane, thus studied, is not in the precise condition of free evolution in the open air.

For this reason investigations have been undertaken on aeroplanes during their free flight in the air. Unfortunately, the field of such investigation is limited. It can not be carried through at the will of the experimenter; that is to say, of the pilot, who must first of all guard against danger of fall. Such experiments give complex results often difficult of analysis. Nevertheless it can not be denied that such results may have a very considerable practical value.

Experiments of this character were inaugurated in 1910 by MM. Gaudart and Legrand with a Voisin biplane. These experiments were, however, neither sufficiently systematic nor numerous to lead to significant results.

Quite otherwise are the researches made by Commander Dorand, at Villacoublay, on a biplane of his own construction piloted by M. Labouchère. At the Institute of Saint-Cyr, MM. Toussaint and Lepère, Toussaint and the Lieutenant of Aviation Gouin, have made important experiments on a Maurice Farman biplane and on a Blériot monoplane. Ingenious apparatus capable of registering the movement of the pilot was employed to furnish important indications regarding the operation of such actual aviation equipment.

5. The Total Resistance of the Air and the Determination of the Pressures at Each Point of the Surface of the Body Under Investigation

Let us return to the methods which, in a laboratory, may be employed in determining the resistance of the air upon a body in movement relative to it.

With regard to the method of measuring this resistance two types may be characterized:

(1) Determination, by means of a balance, of the total resistance on the entire body under investigation.

(2) Determination, at each point of the body, of the reaction exerted by the air at this point; a study, in some manner topographical in character, regarding the pressures resulting from the relative movement of the body and the air.

This investigation immediately leads, through a geometrical composition of the individual forces thus determined, to a knowledge of the complete resistance of the air.

The method by means of the balance has given wonderful results in the laboratory of M. Eiffel and at the Institute of Saint-Cyr. M. de Guiche has applied this method solely to the analysis of the distributed pressures.

Such is the general classification of the experimental methods at present in use in France for the study of the problems of aerodynamics. We proceed to give in detail the fundamental principles of these investigations in a further study of the French aerodynamic laboratories.

CHAPTER II

THE AERODYNAMIC LABORATORIES OF FRANCE

1. The Eiffel Laboratories—Experiments Made at the Eiffel Tower

The Eiffel Tower was the first laboratory utilized by the celebrated engineer in his researches in aerodynamics, carried on during the past ten years. Bodies thrown from one of the platforms of the tower have permitted a study of free fall in calm air.

The study of this movement admits, furthermore, of being made by two different methods.

The first of these methods consists in determining the velocity of uniform movement which succeeds the varying movement. To this velocity corresponds a resistance of the air equal to the weight P of the body. By augmenting the weight of the body without changing the surface, as by the addition of suitable ballast, it is possible to increase, at the same time, the limiting uniform velocity V of the movement. The comparison of the different values of P with the corresponding values of V provides a means for developing a law of variation of resistance as a function of velocity. Such is the principle of the method applied in 1892 by Cailletet and Colardeau from the second story of the Eiffel Tower (120 meters = 394 feet above the ground).

Instead of limiting himself to the study of that part of the free fall that corresponds to uniform movement, M. Eiffel registers the values of the velocity and of the resistance of the air at each instant of the fall. The principle involved in this investigation is the following:

The surface under investigation, a plane for example, falls freely, remaining horizontal. It is supported by a spring, of which the displacements are inscribed on a cylinder revolving with a velocity directly proportional to that of the fall of the system under investigation. The compression of the spring, as a result of the resistance of the air, gives rise to a force which, by a suitable calibration, may be deter-

---

Reprinted from the Second Annual Report of the National Advisory Committee on Aeronautics.

mined as a function of the displacements of this spring. This force produces equilibrium with the following system of forces:

(1) The weight of the system.
(2) The forces of inertia which act upon it.
(3) The resistance of the air.

It is then possible to calculate this last force when the acceleration of the system is known. To this end it is sufficient to inscribe, by means of a tuning fork, the time of fall on the same cylinder whereon are recorded the compressions of the spring.

In a certain experiment, when the combined weight of the plate with its spring and support was 4.494 kilograms (9.887 pounds), the following determinations were made, in one case at the end of 60 meters of fall (196.8 feet) and in the other case at the end of 95 meters (311.6 feet):

At the end of 60 meters:		
Force of inertia........	3.76 kg.	
(Absolute value.)		
Tension of spring......		4.15 kg.
Resistance of the air....		4.90 kg.
Difference		=0.75 kg.
At the end of 95 meters:		
Force of inertia........	3.36 kg.	
(Absolute value.)		
Tension of spring......		6.15 kg.
Resistance of the air....		7.30 kg.
Difference		=1.15 kg.

These numbers show that under the existing conditions (total weight of plates, of spring, and of support rather high) the difference between the tension of the spring and the resistance of the air is clearly measurable.

By this method, M. Eiffel has studied the resistance of the air on planes of which the surfaces varied from 1/16 square meter (0.67 square foot) to 1 square meter (10.77 square feet) and of which the velocities of fall ranged between 18 and 40 meters per second (59 to 131.2 feet). These high velocities have made it possible to operate in the open air with high precision in calm weather and as long as wind velocities did not exceed 2 to 3 meters per second (6.56 to 9.84 feet per second). The results obtained by these experiments are excellent for planes falling horizontally. They are less worthy of confidence for planes inclined to the vertical.

2. The Eiffel Laboratory—Method by the Use of an Artificial Current of Air

This method, which consists in placing a model in the cylinder of air flow created by a fan, should be applied with the following precautions:

(1) It is necessary that the model should be placed in a mass of air theoretically indefinite, practically very great, and having a velocity constant in magnitude and in direction.

The section of the cylinder of air should be sufficiently large, in order that at the periphery the velocity of the air may be sensibly the same in magnitude and in direction as that of the air which has not yet approached the obstacle. In this method it is necessary to realize, first of all, a cylindrical current of air, and then to introduce into this current a body of dimensions so small by comparison that its presence shall not produce any sensible disturbances at the periphery of the current. Experience has shown that the ratio of the greatest dimension of the model to the diameter of the cylindrical current should not exceed 45 per cent.

(2) It is very necessary that the model under investigation shall be practically isolated in the current of air; that is to say, that the support of the model shall play only a negligible rôle and shall introduce no perturbations of importance.

(3) It is necessary that the model adopted shall not be too small in size if it is desired to extend in a more or less significant manner the results obtained with such model to full-sized apparatus.

In fact, when a study is made of the distribution of pressure over the various points of a plate, for example, either on the face directly exposed to the action of the current of air, or on the reverse face, it is found that this distribution becomes regular only at a certain distance from the border. There exists, both in front and behind, a central zone in which a regular regimen is established, which is manifest by isobars parallel to the forward edge. In order that this central zone may be studied, it is necessary that the dimensions of the plate under investigation be sufficiently large. In fact, the width of the marginal zone in which the pressures are irregularly distributed does not vary proportionally with the dimensions of the plate. The experiments of M. de Guiche show that this width varies but little with the dimensions of the plate. In operating on thin rectangular planes with the attacking edge perpendicular to the direction of movement, M. de Guiche has found that the marginal bands of irregular condition have a sensibly constant width, equal to 20 centimeters (7.88 inches) in front and to 40 or 50 centimeters (15.76 to 19.7 inches) at the rear. He concludes that it is well not to operate with planes having a spread less than 1 meter (3.28 feet). In the study of curved surfaces, M. de Guiche found marginal bands of disturbance of which the sensibly uniform width scarcely exceeded 20 centimeters (7.88 inches) on the two faces. It is well, therefore, to use only surfaces whose spreads are superior to 40 centimeters (15.76 inches). When lesser spreads are employed the results obtained by the use of small models do not permit of deducing, in a sufficiently precise manner, the results which would be given by the wings of an aeroplane of normal size. In the case of very small models the mode of distribution of pressure has but a very remote relation to that which would be found on wings of normal dimensions.

This condition of only using, for experimental purposes, models of sufficient dimensions leads, in the method by the use of an artificial current of air, to the employment of very large sections for the cylinder of air. For example, a study of planes having a spread of 1 meter (3.28 feet) can only be made in a cylinder of air of which the diameter is greater than $100/.45 = 220$ centimeters (86.7 inches), approximately. As to curved surfaces, it would be sufficient to provide a cylinder of a diameter greater than $40/.45 = 89$ centimeters (35 inches), approximately.

In France, M. Rateau has utilized the method by the use of an artificial current of air. His apparatus comprises the following items:

(1) A helicoidal fan, 1.2 meters diameter (47.3 inches).

(2) A wooden chamber, 1.5 meters on the side (59.1 inches). The purpose of this chamber is to suppress, by means of suitable partitions, the turbulence produced by the fan and to create a current of air with the velocities of movement equal and parallel throughout.

(3) An outlet orifice of 0.7 meter (27.6 inches) diameter from whence issues a cylindrical current of the same diameter.

(4) A weighing balance located in the outside air at a little distance from the orifice through which the current of air issues.

Such an apparatus would permit of realizing velocities of the air reaching 35 meters (114.8 feet) per second. The diameter of the cylinder of air, however, is too small. M. Rateau was not justified in introducing into this current plates 30 by 50 centimeters (11.8 by 19.7 inches) or biplanes 15 by 50 centimeters (5.9 by 19.7 inches) (separation of planes 20 to 30 centimeters = 7.9 to 11.8 inches). The supports of the objects under investigation and of the measuring equipment were too large, causing very considerable perturbations. The experiments of M. Rateau should be noted as of historic interest, but they can be scarcely considered as having a definitive value.

Much more complete and certain are the results obtained by the installation of M. Eiffel. The Eiffel apparatus comprises the following items:

(1) An orifice from which issues a cylindrical current of air.

(2) An experimental chamber where the air is at a pressure less than normal and where are located the experimenters and the measuring apparatus.

(3) A diffuser.

(4) A fan placed at the end of the diffuser.

The current of air which enters through the orifice in the wall of the experimental chamber and which leaves through the opening of the diffuser placed in the wall opposite and parallel to the first, is a current of air produced by aspiration and not by pressure, as in the installation of M. Rateau. The aspiration removes the influence due to the turbulence produced by the fan, and a regulating box for the current of air in front of the orifice is not necessary. However, certain grillages placed in the openings for entrance to and issue from the experimental chamber play the rôle of regulators for the current of air.

In the laboratory of the Champ de Mars the fan was placed near the opening through which the air leaves the chamber. A large conduit of wood received the air issuing from the fan and, gradually reducing in size, conducted it through a passage ending in the shed, whence the air was drawn into the orifice through which it entered the experimental chamber.

The cylinder of air had a diameter of 1.5 meters (59.1 inches).

The maximum velocity of this air was equal to 18 meters (59 feet) per second, or 65 kilometers (40.4 miles) per hour. The fan employed, of the centrifugal type, delivered 31 meters^3 (1,095 cubic feet) per second, corresponding to a velocity of 18 meters per second and to the circular section of 1.5 meters diameter, requiring 60 horsepower.

The laboratory installed at Auteuil by M. Eiffel is much more powerful. The cylinder of air of the large equipment has a diameter of 2 meters (6.56 feet). Velocities of the air may be realized from 2 to 30 meters (6.56 to 98.4 feet) per second. A second smaller cylinder of air, having a diameter of 1 meter (3.28 feet), parallel to the first, provides velocities from 2 to 40 meters (6.56 to 131.2 feet) per second.

The 60 horsepower is, however, not exceeded in this new installation, in which the delivery of 90 cubic meters of air (3,179 cubic feet) per second may be realized, corresponding to the circular section of 2 meters diameter and a velocity of 100 kilometers (65.14 miles) per hour.

This increase in efficiency is realized by interposing between the experiment chamber and the fan a divergent orifice forming a diffuser. This diffuser has a diameter equal to 2 meters at the outlet from the chamber; it connects with the ring of a helicoidal fan of 3.8 meters diameter (12.46 feet), providing for the flow of the air a useful section of 9 square meters (96.9 square feet). The reduction of velocity which is produced by passing through the diffuser, as a result of the progressive increase in diameter, raises the pressure of the air by a certain quantity and diminishes correspondingly the power which must be furnished to the fan in order to bring the air to atmospheric pressure.

The measure of the total resistance of the air is made in the experiment room by means of a balance, into the detail of which we can not here enter.

The pressures exerted on each point of the body subjected to the action of the current of air are determined by means of orifices of very small diameter fixed normally to the surface at various points of the body and connected with manometers.

This installation likewise provides for determining, with reduced models of screw propellers, the thrust of the propeller and the power required on the shaft. By means of a small electric motor the propeller is turned in the cylinder of air produced by the fan. It is assumed that by this means the same conditions are realized as though the propeller itself advanced through the air.

The propeller models have a diameter which does not exceed 1 meter (3.28 feet). In a cylinder of air of 2 meters (6.56 feet) diameter the propeller model is thus surrounded by a mass of air sufficiently thick to represent action in an indefinite medium.

3. The Aerotechnic Institute of Saint-Cyr

The Aerotechnic Institute of Saint-Cyr was created by M. Henri Deutsch de la Meurthe, who gave it as a gift to the University of Paris. Its purpose is to follow lines of research, both theoretical and practical, tending to the improvement of the means of aerial locomotion in all its forms, these researches being carried out under conditions as nearly as possible similar to those actually in practice.

In order to realize this program, there was constructed on the level a railway 1,350 meters in length (4,428 feet), on which are operated special cars.

The car for the tests of surfaces and of airplanes is an electric tractor with normal gauge. The principal characteristics are as follows:

Weight, not equipped, 5 tons.
Length, 6 meters (19.7 feet).
Width, 2 meters (6.56 feet).
Height, 1.10 meters (3.61 feet).

The current is taken by lateral shoes sliding on conductors placed on either side of the line.

The motor is of 130 horsepower capacity, separately excited. It is geared to two intermediate shafts, upon which are placed pinions which transmit the movement to the forward and rear axles by Renold chains. All the shafts of the motor and axles are provided with roller bearings.

The brake is applied electrically, with a safety provision, by means of shoes at the rear, engaging at the end of the line on a sliding way.

The control is exercised from an operating cab by means of a controller and an adjustable automatic accelerator.

The maximum velocity of the car is about 20 meters (65.6 feet) per second.

The car is furnished with a special mounting providing for registering the following items:

(1) The vertical component force or lift.
(2) The horizontal component force or drift. (These together define the resistance of the air in magnitude.)
(3) A rotating couple, from which, with the preceding, may be derived the location of the resistance considered as a single force.

The relative velocity of the body under trial with relation to the air is determined by measuring the absolute velocity of the car with reference to the ground and adding or subtracting the velocity of the wind according to the direction of the line on which the car runs.

The absolute velocity of the car with reference to the ground is measured by means of a registering speed instrument giving directly the revolutions of an axle. Furthermore, there is installed along the line a system of electric contacts inscribing points of reference on the cylinder of a precision chronograph. This cylinder permits a measurement (to 1/200 second or to 1/10 second) of the time required by the car for traversing a known distance—95.9 meters exactly (314.55 feet).

In order to have the correction due to the wind, measurement is made, at a fixed point on the line where the tests are made, of the magnitude and direction of the wind. The velocity of the wind is measured by an anemocinemographe, which is extremely sensitive (20 millimeters (0.788 inch) for 1 meter (3.28 feet) per second velocity). The direction of the wind is measured by a self-registering wind vane. Furthermore, the correction for the wind cannot

1	R. I. (September, 1909)	40	6.5	1,150	24	36	Touring airship of Herr H. Haase of Hamburg. One Benz engine; one pusher-screw. Designed endurance: 5 hrs. with a crew of three. Ballonet: 230 mc.
2	R. II. (1911)	46	7.4	1,700	75	45	Excursion airship.—One F. I. A. T. engine; one pusher-screw. No lifting planes; height control through a movable weight. Ballonet: 300 mc. Was partly wrecked on landing near Crefeld on June 1st, 1911.
3	R. III. (1913)	65	11	2,700	150	55	Excursion airship.—Two F. I. A. T. engines; twin-screws. Lifting planes. Ballonet: 450 mc.

(Continued from page 289)

[2] Insert grade, first lieutenant, captain, or major.

[3] Insert service in the Regular Army of the United States, or Volunteer forces of the United States, or Organized Militia of any State, Territory, or District of Columbia; also state in what capacity.

[4] Insert name and location of the school or college.

[5] Insert the name and location of the educational institution.

[6] Insert "not" if in accordance with fact.

[7] Oath to be taken before, and signature to be made by, officer authorized by law to administer oaths.

9. Examining boards.—The communication authorizing the examination of the applicant will be sufficient authority when submitted to the president of the examining board before which the applicant will be instructed to appear. This board will consist of from two to five commissioned officers of the Regular Army of the United States, or of regular and reserve officers of the Signal Corps, including at least one and not more than two medical officers. At least one officer of the Regular Army will serve on each board. This board will be appointed on request made by the officer in charge of the aviation section of the Signal Corps to The Adjutant General of the Army.

10. Examination.—Each applicant, except those commissioned in a nonflying capacity, will be subjected to the same physical examination as is required of officers of the Regular Army applying for aviation duty. Those commissioned as nonflying officers will be given the examination required of applicants for a commission in the Reserve Corps of the line of the Regular Army. The mental examination may be omitted, but the equivalent of a college education will be required. The examining board will consider documentary evidence submitted by the applicant. It may seek additional information by practical tests, personal questions, or by procuring additional documentary evidence. Flying ability will be given first consideration, noted and reported in the proceedings of the board. No applicant for a commission as an officer of the aviation section, Signal Officers' Reserve Corps, will be considered proficient until he is able to pass the flying test for Reserve military aviator, unless specially excepted for reasons stated by the officer in charge of the aviation section, Signal Corps of the Army. Candidates for commissions in the aerostatic division, aviation section, Signal Officers' Reserve Corps, must be experienced balloon pilots and qualified as such according to the standard fixed by the International Aeronautical Federation.

11. Proceedings and recommendations of boards.—After the required examination, the proceedings of the board will be forwarded to the headquarters of the convening authority, with the recommendations of the board as to the qualifications of the applicant. The officer in charge of the aviation section, Signal Corps of the Army, will recommend to The Adjutant General of the Army the grade in which each candidate should be commissioned. After appointment by the President, The Adjutant General will issue the commission. These commissions will be in force for a period of five years, unless sooner terminated at the discretion of the President. Such officers may be recommissioned either in the same or higher grades for successive periods of five years, subject to such examination as may be prescribed. All officers will be eligible for promotion upon the recommendation of their commanding officer subject to such examinations as may be prescribed.

12. Duty and pay.—In time of actual or threatened hostilities officers of the Officers' Reserve Corps are subject to such duty as the President may prescribe. The Secretary of War may order reserve officers to duty for periods not to exceed 15 days a year, and while so serving such officers will receive the pay and allowances of their respective grades in the Regular Army.

With the consent of the reserve officers concerned, and within the limit of funds available for the purpose, officers of the Officers' Reserve Corps may be retained on active duty for such periods as the Secretary of War may prescribe.

13. Aviation or balloon students.—In order to qualify for examination as officers of the aviation section, Signal Officers' Reserve Corps, especially qualified citizens of the United States not under 21 nor over 30 years of age who desire to become flyers will be assisted by the United States as follows: To become eligible for obtaining such assistance the person desiring it shall make application to The Adjutant General, who, if the applicant is considered desirable, will cause such applicant to be examined by a board convened for the examination of officers of the aviation section, Signal Officers' Reserve Corps. The board will pass on the applicant's physical, mental, and moral qualifications. The physical test shall be the same as that required for officers of the Regular Army applying for aviation duty. The applicant will be required to establish the fact that he has the equivalent of a college education and to produce evidence of his reliability and good habits. The candidate will be required to state in writing that if he successfully passes his aviation tests he will become an officer in the aviation section, Signal Officers' Reserve Corps. If the candidate successfully passes, the board will so recommend to the War Department. The Adjutant General will then designate the applicant as an aviation or balloon student. When the student enlists in the aviation section of the Enlisted Reserve Corps he will be made a noncommissioned officer and placed on active duty up to the time that his course is completed and he is discharged to accept a commission in the aviation section, Signal Officers' Reserve Corps. Department commanders are authorized to appoint boards of officers to determine whether or not aviation or balloon students, on active duty, are unsuited for the duties of aviation officers, and when such a board finds any student unsuited for aviation training the department commander may cause further instruction to terminate and the student to be relieved from further active duty and returned to his home to await action by the War Department on the question of his discharge. Such school may be either a United States aeronautical school or a civilian aviation or balloon school.

Upon the candidate's satisfactorily passing the reserve military aviator's test he will be eligible for commission as an officer in the aviation section, Signal Officers' Reserve Corps, without further examination.

(To be continued.)

FOREIGN NEWS

FRANCE

The French Ambassador to Switzerland, says a Havas dispatch from Berne, called on the Chief of the Swiss Political Department February 4 to express the regret of the French Government that through an error a French aviator flew over and bombarded the Swiss town of Porrentrui on April 26. He said that an investigation was being made and that proper punishment would be administered as soon as the facts were established. The Ambassador, it is added, offered, in the name of France, full indemnity for the damage sustained.

A dispatch from Berne on April 26 said that an unknown aviator had dropped explosive bombs on Porrentrui. Several buildings were damaged and three persons, including a child, were injured.

A letter from the American escadrille with the French army says that on the morning of April 22 all the American airmen accompanied a bombarding expedition to Essigny and returned safely.

While they were about nine miles within the German lines Raoul Lufbery discovered four German monoplanes, which he believes belong to the "flying circus" that makes a specialty of trapping solitary French airmen. He found himself up against novel tactics when he attacked them. They chased each other in a close circle, so when Lufbery attacked one the others could fire on him from behind.

The American was forced to give up the attempt after trying three times to bring down one of them. Finally one left the others and started to get above Lufberry, but the latter was able to climb so much faster that they all gave up the attempt to trap him and departed.

The American escadrille was cited recently in army orders for its good work. Ray Claflin Bridgman has joined the escadrille, coming from Belfort, where he has had a month's flying experience.

Paris, May 1.—Rene Seitz, a nineteen-year-old French aviator whose mother lives at Senlis, crossed the French frontier from Switzerland today, after escaping from a German prison camp at Lechfeld, Bavaria. He had been there since June 22, 1916, when he took part in the great French reprisal raid on Karlsruhe.

Seitz's aeroplane was riddled with German bullets and his engine struck, forcing him to alight. Sergt. Marcel Maurin of the "Blue Devils," as the Chasseurs Alpine are usually called, and a Russian infantryman accompanied Seitz in his daring escape.

The trio assert that the hatred of Germans against the United States has been fanned into a volcano by the declaration of war, and that many of the lower classes admit the Allies must win now.

GREAT BRITAIN

London, May 6.—A victory by a British air squadron of six machines over a German contingent of between fifteen and twenty 'planes is recorded in to-night's official statement.

The Germans, flying in several groups, attacked the British airmen and succeeded in breaking up the squadron formation. But the British pilots continued to support each other and brought their machine guns into effective play. One of the German machines was brought down just within the British lines.

Then the fight shifted over the enemy's territory, where two more hostile machines were seen to drop and crash. Finally two others were sent down out of control, whereupon the remainder of the German squadron fled. Though considerably battered, all the British machines returned to their base.

Altogether yesterday the British, at the cost of two of their own machines, destroyed four hostile 'planes, threw five out of control and shot down two more by gunfire.

Paris reports three German aeroplanes brought down by French fliers and an other by gunfire. In a raid on Hagondange 8,500 kilograms of projectiles were dropped on stations, barracks and factories, causing extensive fires.

Berlin declares that the Allies lost fourteen aeroplanes yesterday and two captive balloons.

London, May 2.—In the House of Lords today the the Archbishop of Canterbury raised the question of the recent bombing of Freiburg by French and English aviators in retaliation for outrages perpetrated by the German fleet. The Archbishop declared there was a strong feeling throughout the entire country against such reprisals.

Earl Curzon, member of the War Council, replying for the Government, said that after the "abominable outrage" against the hospital ship Asturias, the War Cabinet had decided to execute the threat of reprisals made in January.

"We consulted the French upon the matter," Earl Curzon continued, "and they heartily approved of the plan, and expressed a desire to co-operate. It was then decided to carry out the bombing raid on Freiburg. The Government, however, consulted the Imperial War Conference, which also concurred, and it was also decided that no reprisals would be undertaken after this if the Germans ceased their attacks on hospital ships."

It was too early, Earl Curzon added, to say whether the reprisal had been successful, but there was evidence that it had a salutary effect. He said the French had announced they would put German prisoners on their hospital ships.

An official British Admiralty statement issued on April 16 said that in consequence of German submarine attacks on British hospital ships a large squadron of British and French aeroplanes had carried out a reprisal bombardment on the previous Saturday on the German town of Freiburg, and that many bombs had been dropped with effective result.

The following day the Berlin War Office said eleven persons had been killed and twenty-seven injured in the air raid. Among the dead were seven women, three men, and one soldier. Seventeen women, eight men, and two children were wounded.

The Admiralty announces that the British steamer Gena, 2,784 tons, was sunk May 1 by a torpedo discharged by a German seaplane off Adelburg (Suffolk, England). All hands were saved.

Another seaplane concerned in the attack was brought down by the gunfire from the Gena and its crew made prisoner.

Berlin (via London), May 2.—An official statement issued to-day says:

‘A few seaplanes attacked on Tuesday morning enemy merchant ships before the Thames and sank a steamer of about 3,000 tons. One of our machines failed to return and is supposed to have been lost."

A compilation from British, French and German official communiques shows that 717 aeroplanes were shot down on the western front during April.

The Germans lost 369, the French and Belgians 201, and the British 147. This is a great increase over the casualties for any similar period. The highest previous total was 322 during last September.

ITALY

London, May 3.—The Italian War Office issued to-day the following report:

On the whole front there were the usual artillery actions yesterday and somewhat greater activity on the part of our patrols, which engaged in minor fights. Last night enemy aviators dropped bombs on the training establishments and dwellings at Codigoro. One of our aerial squadrons renewed the bombardment of the military works at Opcina and Prosecco. A squadron of six aeroplanes dropped ten bombs on Avlona (Albania) without causing casualties or serious damage.

JAPAN

The Imperial Aviation Association's biplane of a smaller type which was under construction at Tokorozawa has been completed. The construction of this new aeroplane, which is the design of Mr. Y. Ozaki, son of the ex-Minister of Justice and airman belonging to the said Association, was started on account of the handsome donation amounting to 10,000 yen of Mr. Soga, stock broker in Osaka, and has been christened "Soga," after the name of the donor. The "Soga" 'plane is equipped with Mr. Shimatsu's 90 h.p. engine and can make 70 miles an hour. It will be remembered that in order to encourage the construction of home made motors, the Imperial Aviation Association some time ago offered a first prize of 20,000 yen, and Mr. Shimatsu's motor has been allotted premier place. Mr. Ozaki will pilot the machine, the trial flight of which is reported to be made in Osaka about the middle of this month.

One of the large reconnaissance machines used by French Flying Corps

Bulletin, Broadway Model Aeroplane Club of of Baltimore, Md.

Mr. W. H. Logue, Jr., 931 North Broadway, Baltimore, Md., has offered a set of prizes for a series of model aeroplane contests, to be held at a date to be later announced. Trophies of various kinds will constitute the prize list—cups, banners, medals, and gold coins of $5, $10, $20 cash. Awards will be for distance and duration. It all depends on the interest and enthusiasm aroused, and all club members are urged to spread the news so that entries can be secured at the earliest moment. Any young man in the State of Maryland is eligible to compete. No charge of any kind will be made. The only requirement is that any person desiring to enter the contest build and fly a model aeroplane that he has constructed himself. Show your ingenuity and take a chance at the latest and greatest sport in the world. Use your own ideas and you may help to revolutionize the art of flying. It is great sport and it brightens the brain. Until you try you can't tell whether you are an American eagle or only an English sparrow, so take a chance and try your wings and see. Mr. Logue also offers to pay all expenses of a trip to New York so that some Baltimore boy can compete with the delegates from other clubs that will enter model aeroplanes in the National Contest. An opportunity to enjoy the greatest sport in the world today, and an acquaintance with the brightest boys in Maryland, is something that you should take advantage of, especially as no expense is incurred. Communicate with Mr. W. H. Logue, Jr., 931 North Broadway, Baltimore, Md. Telephone Wolfe 2338 direct, or C. Howard Black, secretary Broadway Model Aeroplane Club of Baltimore, Md., for further information. Send name and address for later bulletins. Tell your friends.

The Indiana University Aero Science Club

The first business meeting of the Indiana University Aero Science Club was held on Friday evening, April 27th. Twenty-two members were present and about a dozen visitors. Mr. Tobias Dantzig of the Department of Mathematics was elected president, and Mr. B. Shilling, secretary-treasurer.

Mr. Dantzig, who for a year worked in the Ecole Supérieure d'Aëronautique of Paris, will offer a course in elementary aeronautics. The members of the club will be grouped into teams of five and each team will undertake to construct a scale model of an aeroplane of standard type. Flying contests will be held before commencement.

The Triangle Model Aero Club

At a recent meeting of the Triangle Model Aero Club of Baltimore, Md., the following officers were elected: Mr. Arthur Waugh, president; Mr. John White, vice-president; Mr. Hurburt Collier, treasurer; Mr. Charles G. Crockett, secretary.

It was also decided at the same meeting that all contests would be held at the Trial Grounds, Colgate, Baltimore, Md.

Every member has pledged his heartiest desire to co-operate in the interest of the club and the advancement of the science of aeronautics in general. Any young man in the neighborhood of our club who is interested in aeronautics and who feels that he would like to associate with us and work for the cause, just drop a line to Mr. Charles G. Crockett, Secretary, Colgate, Baltimore, Md. All applications for membership will be given prompt consideration.

Kites

That Mr. Samuel F. Perkins, of Boston, the veteran pioneer kite flyer, is as active as ever in the interests of kite flying is evidenced by a report in the *Official Gazette* that a patent for a new type of kite has just been granted Mr. Perkins.

In communicating with Mr. Perkins concerning this new and interesting kite he replied stating that in the very near future he would send us a complete detailed description of his new invention for the benefit of our readers.

There is hardly an aeronautical enthusiast in the country who does not know of Sam Perkins and his kites and the presentation of the description and photograph of his new kite will doubtless be of interest to all.

Mr. Henry Villard to Offer Another Trophy

Mr. Henry Villard, who donated the trophy for mechanical driven models which was contended for during the past two years and which was won both times by the Illinois Model Aeroplane Club, is again anxious to stimulate interest in the mechanical driven model, and will offer another trophy.

Just what the plans for the contest will be have not yet been decided upon, but there is an indication that the competition will be open to all.

Full details of the contest will be published in a forthcoming issue.

Another indication of model activity in the West. Here we see the members of the Model Aero Club of Nebraska lined up with their models just after they held their first contest. Dr. F. C. Buck, of Lincoln, Nebraska, is in a large measure responsible for the rapid progress made by the members of this club and through his assistance it is quite possible that many interesting model events will take place in this city

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested

Extra Precautions

Captain—Well, Lieutenant, I would like to know what you do in these times to see that our men get nothing but the purest of water to drink.

Lieutenant—Well, Captain, first we boil it.

Captain—Excellent!

Lieutenant—Then we filter it.

Captain—Very good!

Lieutenant—Then we distill it.

Captain—Very good, sir, I congratulate you!

Lieutenant (aside)—Then we drink beer.

Valiant Six-Hundred!

President of the Electric Light Company, making his annual Fourth of July oration in the town hall—"I can not understand how people can joke about our light company. Think of the benefits we give to the people. Think of the light, heat and power we furnish. Why, in fact, you could not do without us! If I may use the words of the immortal Tennyson, 'Honor the Light Brigade!'"

Voice from the back—"But think of the charge they made!"

Further Advice for Aeroplane Enthusiasts

1. Make it a rule to ask the busiest man in the shop your questions. He is so overworked that it will be good for him to rest awhile and answer your questions.
2. Ask the designer to let you have a look at his latest blue-prints. When you see them, look them over and tell him that you don't think they amount to much.
3. Assist the workmen all you can. If you see one of them that isn't doing his work right, tell him so, and he will appreciate it.
4. Don't let any signs saying to keep out, bother you. They were not put there for you. You are always welcome.
5. Go up to the chief engineer and lay your latest invention before him. Even if you haven't worked it out yet, tell him the general idea.
6. Above all, if you represent a magazine, solicit advertising just when they are busiest. They like to spend their money, and you might as well get it as anyone else.

Hashimura Outdone

We resign forevermore any thoughts we may have possessed that we could write Japanese dialect. With Wallace Irwin as a model, we have dabbled with Hashimura Togo, and were actually beginning to believe that our stuff was fairly funny. *BUT*. We will quote directly from *The Aeronautic World* of Tokyo, Japan, with the final word that, in our opinion, the writer could not have been any funnier if he had sat up all night practising.

AVIATOR TATEISHI RETURNED HOME

The licensed aviator Mr. S. Tateishi, who had returned from America recently made a flight in Owari prefecture on the 3rd of March. When he fly up about 50 meter some trouble occured in the machine and fell on the ground. He briskly jamped off from the seat an could fortunately landed uninjured. He will made the greatest cross-country flight in Japan shortly.

THE GRADUATION FLIGHT OF THE ARMY

The graduation flight was held on the March 1st at 7.35 a.m. Left. Matsuoka by M.F. 31, Sub-left Kamiya by M.F. 43, and Sub-Left. Wada by M.F. 44 left the Tokorazawa aerodrome and arrived at the Mizurbari ground in Mito at 9.18 a.m. In the afternoon they returned to Tokorazawa.

The 2nd of March, at 7.38 a.m. Left Watanabe by M.F. 31, Sub-Left. Noda by M.F. 43 and Sub-Left Hishinami by M.F. 44, started to Mito with a minute interval, 9.40 Sub-Left Noda and reached the destination at 9.23. (*Some traveling! They left at 9.40, and arrived at 9.23!*—ED.) M.F. 31 drived by Left. Watanabe, on her way back the machine missed fire from the engine and he was obliged to descend to the field. The machine was disconnected and brought back to Tokorazawa by train.

(By this it would seem that every one had a perfectly splendid time except the unfortunate driver of the machine which missed fire from the engine.)

Important Note

To tell the truth, we could not think of anything sufficiently funny to insert in this space, and rather than perpetrate on our readers anything other than the funniest of the funny, we have hit upon a plan. We hope that by some measure it will prove feasible. This is it:

Think of the funniest joke you have ever heard in all your life, and then imagine that you were looking at it in this space for the first time. And if your joke is really funny, you will laugh your head off. No?

THREE MEDALS OF MERIT were awarded by the Aero Club of America for the following notable records:

J. FLOYD SMITH, who created three new World hydro altitude records in a Martin seaplane: January 12, 1916, with one passenger, 12,333 feet; January 11, 1916, two passengers, 9,524 feet; February 16, three passengers, 9,608 feet.

C. C. CULVER, Captain, U. S. A., for his great achievements in developing wireless equipment for sending and receiving messages from aeroplanes. All his experiments and achievements were made using a Martin Military Tractor Biplane.

A. D. SMITH, Corporal, U. S. A., who created a new hydro duration record February 19, 1916, in a Martin seaplane by remaining in the air 8 hours and 42 minutes.

Many other performances of note prove the certainty and efficiency of our designing and the superior construction of our aircraft.

THE WILSON CABINET COMPANY announce that they have a large plant containing 50,000 feet of floor space, with equipment ready to immediately manufacture aeroplanes of all types to specification. Correspondence invited concerning details of the facilities available.

WILSON CABINET COMPANY
NASHVILLE, TENNESSEE

(*Continued from page* 293)

be made with satisfactory rigor unless the average velocity of the wind is at least equal to 2 meters (6.56 feet) per second.

A car of the same type as the preceding, but more robust, serves for the study of an entire aeroplane. These experiments, still in an introductory stage, have been carried out on a two-passenger machine of the Blériot type. The characteristics of this monoplane are as follows:

Tail plane (pigeon tail).
Span, 11.10 meters (36 feet).
Length, 9 meters (29.5 feet).
Surface of the wings, 25.35 square meters (272.8 square feet).
Angle of the chord of the wings with the tail plane, 6°.

The ensemble of this apparatus was studied for three positions of the depth rudder:

(*a*) Rudder in the prolongation of the tail plane.

(*b*) Rudder turned 18° downward with reference to the tail plane.

(*c*) Rudder turned 51° upward with reference to the tail plane.

Experimental speeds 15 to 18 meters (49.2 to 59 feet) per second (54 to 65 kilometers (33.5 to 40.4 miles) per hour).

A special car serves for the study of propellers.

The propellers are full sized. They are mounted on the special car which they serve to propel. This car carries a framework which makes it possible to carry the propeller at a distance from the car itself and to operate the propeller as though it were placed in an indefinite medium. On the car is an 80-horsepower motor which operates the propeller shaft by means of a transmission similar to that which is found on dirigible balloons.

The axles of the car are free and the speed of the car is due solely to the pull of the propeller. A lever brake is provided which is applied by the operator who rides on the car. This brake is, furthermore, similar to that which is used on the car for testing surfaces. The control of the car is carried out from an operating cab similar to that for the car previously described.

The return of the propeller car is obtained by running the propeller backward at reduced speed in order to avoid undue strain. The pull of the propeller is measured by means of a dynamometer inserted between a movable bar articulated at its base and the fixed framework of the car.

The power absorbed by the propeller is measured in two different ways:

(*a*) By means of a wattmeter registering the electric power required by the motor.

(*b*) By means of a transmission dynamometer registering the couple required to drive the propeller.

These two pieces of apparatus are standardized by means of a Renard brake, which is attached to the shaft in place of the propeller.

The velocity of the car is determined by the same two methods as above noted for investigating surfaces.

The number of revolutions of the propeller is measured by means of a registering counter.

The relative velocity is obtained by making a correction for the wind, the same as in the case for surfaces.

The velocities realized have not exceeded 20 meters (65.6 feet) per second.

The Aerotechnic Institute has undertaken to make a series of tests on aeroplanes in free flight.

M. Toussaint, assistant director of the institute, has carried out the following investigations:

First, on a Maurice Farman biplane, piloted by Capt. Etévé.

Second, on a Blériot monoplane, piloted by Lieut. Gouin.

The following items of equipment were installed:

(1) A recorder of relative velocity giving the speed of the aeroplane relative to the air.

(2) A registering wind vane giving the inclination of the wind to the chord of the planes.

(3) A registering clinometer giving the longitudinal inclination of the aeroplane relative to the horizontal.

(4) A registering barograph, very sensitive up to 500 meters.

(5) A registering revolution counter giving the speed of the engine.

(6) A register of the movement of the depth rudder.

(7) A register of the warping of the planes.

All these registering instruments, except the revolution register, are provided with cylinders of such proportions as to give a length of diagram of 292 millimeters (11.5 inches) in 26 minutes—that is, 11.2 millimeters (0.442 inch) per minute. With this velocity of movement of the record one may judge the periods of steady conditions exceeding 10 to 20 seconds duration. Quantitative measures can not be properly drawn from periods of steady condition having less than this duration.

In order to assure a perfect agreement in time between the different diagrams, or, in other words, in order to be perfectly sure that the points taken as corresponding do indeed relate exactly to the same instant of flight, each register is provided with a supplementary pen moved by an electromagnet. Throughout the course of the flight the pilot by closing the circuit at sufficiently close intervals causes these pens to register simultaneously on all the diagrams.

The reference points thus traced are all in synchronism, and thus provide an assurance of perfect accord for measurements made in the vicinity of these points.

In order to protect the instruments from vibrations and shocks, they are provided with elastic suspension in their cases.

We shall not enter into the details of the description of these various instruments. We note simply that the register for velocity relative to the air, as well as the direction vane, should be placed in such manner as to avoid the turbulence produced by the propeller, the planes, and the body.

The register for the movements of the depth rudder and for the warping of the planes was installed on the Blériot. This gives on one cylinder the movements of the handwheel barrel. It comprises simply a system of axes with tracing points, parallel between themselves and perpendicular to the axis of the registering cylinder. Each one of these axes carries, on the one hand, a lever connected to the barrel by a wire, and, on the other hand, a stylus or marking pen. A return spring fixed on the lever serves constantly to maintain the wire under tension. This wire is attached to the barrel at the same point as the cable which operates the corresponding control; it passes over little pulleys and is thus carried to the register. The movements of the stylus for the position of the barrel corresponding to horizontal flight and to various inclinations of the depth rudder are marked on the register, the axis of the propeller in repose being horizontal. Similarly reference marks are determined in repose for the movements of the stylus registering the warping movements of the planes. In the apparatus of the institute the needle rises when the barrel is carried to the left; it descends when it is carried to the right.

The Aerotechnic Institute possesses also an installation for the study of small models by means of a fan. The fan absorbs 120 horsepower, providing for a flow in an experimental section of 2 meters (6.56 feet) diameter of a current of air of 40 meters (131.2 feet) per second or 144 kilometers (89.4 miles) per hour. The total delivery amounts to 125 cubic meters (4,412 cubic feet) per second. This apparatus is under trial.

There is also at the Institute of Saint-Cyr a covered installation for the study of small models. The diameter of the rotunda is equal to 38 meters (125 feet). The turning arm is about 16 meters (52.5 feet) in length. The velocity at the extremity is 90 to 95 kilometers (56 to 59 miles) per hour.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

PERFORMANCE

The New York Aero Construction Company's Twin Motored Seaplane has a maximum speed of 85 miles per hour, excelling the estimate by ten miles per hour. Yet it has a slow landing speed of 43 miles per hour, allowing the landings to be made within a much smaller space than is ordinarily the case. But what is even more important in coast defense work is the fact that it has a

FLYING RADIUS OF NINE HOURS

The advantages of a high speed and a wide flying range are obvious. The coasts of the United States are long, and the swifter the machines that guard them, and the longer they can stay in the air, so much better and more easily are the coasts patrolled. The seaplane mentioned in the editorial of the World could, flying at full speed for its seven hours' flying radius, cover 515 miles. The seaplane of the New York Aero Construction Company could cover 680 miles.

820 Sq. Ft. Supporting Surface.
Two 100 H.P. Aeromarine Motors.
Weight 2,700 lbs. Useful load 1,700 lbs.

Maximum speed, 85 Miles per hour.
Minimum speed, 43 Miles per hour.
Flying radius, nine hours.

Designed and constructed throughout under the supervision of Mr. Warren S. Eaton.

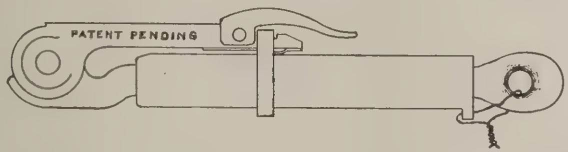
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

Burgess Training Hydroairplane

Among the many models of Airplanes, Seaplanes and Flying Boats produced by this company the new "U" type Hydroairplane meets a very pressing need—an efficient, well-balanced flying machine of conventional type and low power for militia training purposes.

The Massachusetts Naval Militia has the first one now in service.

Standard Deperdussin control in duplicate; Curtiss OXX-2 motor; simple float; light, sturdy construction; large speed range (forty to sixty-eight miles per hour); are characteristics necessary to the hard service required for training purposes.

Hydroplanes and pontoons designed and manufactured for airplanes of every type, including Curtiss, Sturtevant and other makers.

Designers and constructors for the U. S. Army and Navy and British Admiralty.

Aeroplane Spruce

Close, Straight Grain, 4 Sides Clear

Guaranteed to be the Finest and Strongest aeroplane timber offered

PRICES ON APPLICATION

All price quotations withdrawn. There has been a rise of ten to twenty-five dollars per thousand feet on all classes of this lumber during the last thirty days, and the probabilities are that the grade 3 inches thick and thicker, 6 inches wide and wider, ten per cent; 10 to 17 feet long, ninety per cent; 18 to 40 feet, seventy-five per cent vertical grain, **four sides clear** straight grain, not less than ten annular rings to the inch, will be $200.00 per thousand f. o. b. New York within sixty days. Many foreign buyers are on the Pacific Coast and are taking all offerings. It is advisable to place contracts at once for a season's supply before the price rises further or the grade is exhausted. No aeroplane spruce older than 4 to 6 months is available and spruce should be air dried nine months and longer to achieve the best results. In purchasing, care should be taken to buy from a specialist the grade known as **four sides clear, free from all knots and sap pockets.** Some aeroplane builders not conversant with these specifications have made purchases which were practically valueless for construction work.

FIRE-PROOF YOUR AEROPLANE

REMARKABLE NEW AEROPLANE DOPE AND REAL FIRE-PROOF PAINT
that meet every standard requirement, and in addition

INSURE FIRE PROTECTION

This remarkable new Dope, besides being absolutely fire-proof, will by our process render your plane fabrics

Drum Tight and Strong, Absolutely Smooth, Water and Weather-Proof and is Non-Poisonous in Application, Tough and Flexible, with Proper Shrinkage Allowance, and our

REAL FIRE-PROOF PAINT

WILL ABSOLUTELY PROTECT YOUR WOODWORK AGAINST FIRE

Oil and gasoline spilled or splashed on plane surfaces, if ignited by engine backfire, cannot burn fabrics treated with our new dope—the fire cannot touch the fabric and will not spread beyond the oil covered area.

SPAR VARNISH REMOVER

We also make a "cleaner" or spar varnish remover with which spar varnish can be easily and quickly removed **without in any way affecting** the under coating of our special fire-proof dope. It makes the re-doping of any part or the whole of a surface a simple and easy matter and eliminates the necessity of disassembling and reconstructing the part affected, with a saving and economy that can be readily appreciated.

MAY WE AFFORD YOU THE OPPORTUNITY OF MAKING A CONCLUSIVE DEMONSTRATION FOR YOURSELF

A Lewis Machine Gun in action against
a hostile aeroplane

U. S. Senator BRADY: "Have we developed a first-class type of machine gun?"

Major-General LEONARD WOOD: "The Lewis gun has been adopted practically unanimously as the light gun of the British service and is being built for the French; and I think it is safe to say, when you see great nations struggling for life adopt a gun, that they are not adopting it lightly."

Transcript from the hearing before the U. S. Senate Military Committee, January 31st, 1917.

Instruction Machines of the U. S. Army Somewhere in America

Army Has $65,000,000 for Aeronautics—$125,000,000 Required to Carry Out Plans

A Lewis used as an anti-aircraft gun masked in wheat field
Official photograph (Crown copyright) taken on the front in France

"MODERN Warfare has developed a real necessity for machine guns both light and heavy, but as far as I saw, the Lewis Gun far outnumbered all other machine guns of the light type among the Allied armies.

"In the last engagement I saw in the recent Somme offensive, whole detachments were going into the trenches with every man carrying a Lewis Gun as one would carry an ordinary rifle."

THREE MEDALS OF MERIT were awarded by the Aero Club of America for the following notable records:

J. FLOYD SMITH, who created three new World hydro altitude records in a Martin seaplane: January 12, 1916, with one passenger, 12,333 feet; January 11, 1916, two passengers, 9,524 feet; February 16, three passengers, 9,608 feet.

C. C. CULVER, Captain, U. S. A., for his great achievements in developing wireless equipment for sending and receiving messages from aeroplanes. All his experiments and achievements were made using a Martin Military Tractor Biplane.

A. D. SMITH, Corporal, U. S. A., who created a new hydro duration record February 19, 1916, in a Martin seaplane by remaining in the air 8 hours and 42 minutes.

Many other performances of note prove the certainty and efficiency of our designing and the superior construction of our aircraft.

VOL. V NEW YORK, MAY 21, 1917 No. 10

ARMY HAS $65,000,000 FOR AERONAUTICS—$125,000,000 REQUIRED TO CARRY OUT PLANS

CONFIRMING the recent reports printed in AERIAL AGE regarding the large appropriations for military aeronautics, the *Army and Navy Journal* says editorially:

"While the efforts of the Signal Corps for the time being will be directed entirely to the problem of supplying the forty-eight aero squadrons and eight balloon companies to complete the tactical composition of the first Citizen Army, it is learned that work already is under way on a three-year program which will call for at least 2,500 trained aviators and a ready-for-use air fleet of 3,700 'planes. Tentative estimates show that $125,000,000 will be required to carry out these plans. The Signal Corps, however, have available today not less than $65,000,000 to be expended on aviation and no doubt is felt on the question of getting as much more in the next two years.

"Absolute assurances have been given Brigadier-General George O. Squier, C. S. O., that sufficient training machines will be ready when his student forces are gathered. The question of fighting aeroplanes is a more weighty one and *it is more than probable that the equipment of the aviation force sent to Europe will come from French factories.* The statement that no American model has yet been found that is equal in every way—speed, endurance and general flying capability—to the demands of modern air fighting, remains unrefuted so far as we can learn. British experts candidly told our aviators that their machines are too small and too slow for either reconnoisance or raiding. Recent unfortunate accidents to our student-aviators indicate even graver troubles.

"Major Tuslane and Lieutenant de la Grange, two French army aviators, have reported to General Squier with a view to offering their services in the work of building up the American aviation service. The visiting officers have been assigned desks in the office of the C. S. O. and were in daily conference with him.

"Authority has been given for the organization of the 1st and 2d Reserve Aero Squadrons at New York City and Philadelphia, respectively. The commanding general of the Eastern Department was instructed to complete these units by the assignment of officers and enlisted men from the Aviation Section, S. R. C."

We do not agree with the *Army and Navy Journal* in its conclusions regarding American fighting machines and refer this contemporary to the recent reports regarding the comparative efficiency of European and American machines. We can supply aeroplanes equal type for type to the best European machines, and heartily hope that the authorities will not lose this opportunity for creating greater sources of supply.

To place orders in Europe for aeroplanes to be used by American aviators is not only a case of adding work instead of helping our Allies, but it leads to shirking our duty, which is to develop and supply aeroplanes equal to the very best European products.

The temper of the country at present is not such that it will permit shifting on our Allies responsibility which we should assume ourselves, or failing to promptly take steps to create adequate sources of supply in this country for such necessary instruments of war as fighting aeroplanes are. If it should happen that our Allies should have a more efficient machine in any given type, then it is the duty of our authorities to secure these designs and make them available to our manufacturers. In the meantime we should supply our Allies with a large number of machines of the type which they are using and need in large numbers for submarine hunting. The American machines of this type are superior to the European and the Allies need many. Let us begin by solving the most pressing problems and act promptly.

F. H. RUSSELL ELECTED PRESIDENT OF AIRCRAFT MANUFACTURERS' ASSOCIATION

MR. F. H. RUSSELL, the veteran aeroplane manufacturer, manager of the Burgess Co., was elected president of the Aircraft Manufacturers' Association at its regular monthly meeting, which was held on May 9 in the offices of the Association, 501 Fifth Avenue, New York.

The following were present at the meeting: Aeromarine Plane & Motor Corp., represented by Mr. Inglis M. Uppercu; Burgess Company, represented by Mr. F. H. Russell; the Curtiss Aeroplane and Motor Corporation, represented by Mr. Fay L. Faurote; L-W-F Engineering Co., represented by Mr. A. H. Flint; Standard Aero Corporation, represented by Mr. Harry B. Mingle; B. F. Sturtevant Company and the Sturtevant Aeroplane Co., represented by proxy; Thomas Morse Aircraft Co., represented by Mr. H. B. Morse.

Election of officers was held and the following were elected: Honorary President, Glenn H. Curtiss; President, Mr. Frank H. Russell, Burgess Company, Marblehead, Mass.; Vice-President, Mr. Albert H. Flint, L-W-F Engineering Co., College Point, L. I.; Treasurer, Mr Inglis M Uppercu, Aeromarine Plane & Motor Co., New York City; Secretary, Mr. Benjamin L. Williams, New York City; Assistant Treasurer, Mr. A. H. Flint.

Mr. Russell succeeded Mr. H. B. Mingle, the provisional president, who resigned.

Resolutions of appreciation for Mr. Mingle's past services to the Association were passed, and as a token of the personal appreciation of the members for him, he was presented with engrossed resolutions and a handsome gold watch suitably engraved.

Six committees were authorized as follows:

Advisory Committee: Albert H. Flint, H. B. Morse, Benjamin Foss.

Committee on Patents: Curtiss Aeroplane & Motor Corp. Chairman, Thomas-Morse Aircraft Co., Sturtevant Aeroplane Co.

Committee on Materials: L-W-F Engineering Co. (Chairman), Curtiss Aeroplane & Motor Corp., Burgess Co., Standard Aero Corp., Sturtevant Aeroplane Co., B. F. Sturtevant Co., Aeromarine Plane & Motor Co., Thomas-Morse Aircraft Co.

Membership Committee: Benjamin Foss, H. B. Mingle, Mr. A. H. Flint.

Standardization Committee: Curtiss Aeroplane & Motor Corp. (Chairman), L-W-F Engineering Co., Burgess Co., Standard Aero Corp., Sturtevant Aeroplane Co., B. F. Sturtevant Co., Aeromarine Plane & Motor Co., Thomas-Morse Aircraft Co.

Publicity, Advertising and Censorship Committee: Fay L. Faurote.

Resolutions were passed authorizing the insertion in all advertising of the members the following line "Member of the Aircraft Manufacturers' Association" and a resolution of appreciation for work of Mr. H. B. Mingle, who as president did much to firmly establish the Association in its chosen field. It was also resolved to create a design typifying the aircraft industry to be used as a distinctive mark of the Association. In addition there were a number of other important matters in connection with the industry that were considered, the details of which are not available as yet. The meeting adjourned at 6:30 P. M. to meet again on June 13th.

President Russell does not need introduction to the aeronautic movement. He has been in it since the earliest days, first with the Wrights and then in charge of the Burgess Co. A Yale graduate and a man of remarkable abilities and extensive experience, Mr. Russell is especially fitted to be the president of an organization having such a splendid future as the Aircraft Manufacturers' Association has. Above all, he holds the confidence of all the aeronautic manufacturers and workers who will gladly co-operate with him in the co-ordinating of efforts and resources for the advancement of American aeronautics and the upbuilding and extending of the Association's prestige and power.

LONDON PRESS WELCOMES SUGGESTION TO SEND AMERICAN AVIATORS TO EUROPE

The London press has welcomed the suggestion to send American aviators to Europe. In an editorial entitled "America and the War" the London *Daily Telegraph* says:

"According to our New York correspondent, in the interesting communication which we published on Saturday, it is probable that the first contribution of America to the fighting forces at the front will consist of 'a large, representative and enthusiastic corps of military aviators.' *We hope that prognostication, which was based on statements made by leading members of the Aero Club of America, may be fulfilled at the earliest possible moment. There is, indeed, already at the front a squadron of American fliers, known as the Lafayette Squadron, which for more than a year has shared to the full at Verdun and elsewhere, the perils and glories of the Royal Flying Corps and their French colleagues.* It was announced a few days ago that the members of this squadron had just been officially recognized by the American Government, and would for the future wear American uniforms. It may be assumed, therefore, that the American authorities will keep this squadron for the future up to its full strength, and any additions they can see their way to make will be heartily welcomed. Naturally, there is an eager desire in this country, now that America has come into the war, to have an opportunity of saluting the American uniform, and many people, apparently, seem to think that merely by touching a button an American Expeditionary Army will spring into being, ready to step on board the waiting transports. They remember how instantly three divisions of the British Expeditionary Force were got ready and sailed for France at the beginning of the war, and they seem to expect the United States to repeat the same feat. They forget, however, that it was the settled military policy of Great Britain to have its spearhead ready for instant service in any part of the Empire, whereas the very last thing contemplated by American statesmen and the American military authorities can have been the despatch of an American Army, whether large or small, to fight on the battlefields of Europe. The United States has maintained a regular standing Army small out of all proportion to its population, wealth and power; so exiguous, indeed, that the Germans, accustomed to think of armies in terms of millions of men, regard it as a ridiculously negligible quantity. Doubtless it is in their eyes, but another 'contemptible little Army,' which they need not take into their reckoning, and which, as a matter of fact, they deliberately ignored when they decided to prosecute their submarine policy to the utmost, regardless of whether it led to a rupture with America or not. It is, of course, for Americans themselves to determine what military steps they will take to aid the common cause. They are resolved on raising great armies. They will require the cadres of their Regular Army for the purposes of easy and rapid expansion. Let it be remembered how enormously useful the cadres of our Regular and Territorial battalions were to Lord Kitchener at the beginning of the war, and what use he made of them when he set about raising the New Armies. Our latest Allies are in much the same position as we were then, and, therefore, it is quite certain that they will use their Regular Army as the nucleus of the great new American Army, which, if the war lasts long enough, will help in administering the coup de grace to the common enemy.

"They might, no doubt, send a small force, just to show the American flag at the front. That would appeal magnetically to the sentiment of all America's Allies, and if an American Brigade or Division does cross the Atlantic, as an earnest of the great army which is to follow later, the people of England will welcome it with the same heartiness which they showed to the brigades and divisions of our own Dominions. The notion, however, is rather a sentimental one, and there may be vital military objections to it from an American point of view. Much, therefore, as we should like to see the spectacle of an American Division marching through the streets of London, with the Stars and Stripes flying, and warmly as London's millions would respond to the sight, we shall not be surprised if the American authorities decide not to send any military forces to Europe until they can despatch an army commensurate with the power and authority of the United States. That Army will need to be equipped with is proper quota of flying squadrons, and the aviation establishment of the American Army was until lately framed on a very small scale. The Government, however, recently increased the vote for the aerial service from $300,000 to $3,625,000, and large aviation training camps are being formed, where preliminary training can be given. The officials of the Aero Club told our New York correspondent that applications were pouring in, and that there will be no trouble to get a thousand volunteers to make up American aero-squadrons, like trained battalions, are not be had ready made, simply by stamping on the ground, and we must not expect too much even from the American genius for improvisation and obtaining lightning results. Nevertheless, we hope that the first reinforcements to the Allies from America—apart from such useful aid as may be rendered at sea—will take the shape of aero-squadrons, eager to carry on the fine tradition already established by the Lafayette Squadron. Be the unit what it may, and come when it may, the American fighting uniform will be greeted with rapture in whatever part of the United Kingdom it is seen, and those who wear it will be made to feel that they are among their own people. Anglo-Americans do not disdain sentiment when they meet together at luncheon or dinner and listen to eloquent speeches. Give the mass of Londoners a chance of saluting 'Old Glory,' borne by American soldiers who have come to Europe to fight for Freedom at the side of British and French soldiers, and the enthusiasm of last Thursday will be rekindled at every street-corner."

Checking the Submarine Menace

The submarine menace can be checked by present-day airchaft.

In any discussion of what can be done against the submarine, there must first be stated whether we mean the protection of ships at sea or when they are on coastwise trips. Nothing else could protect the sea lanes so well as large dirigibles, capable, as the Zeppelins are, of cruising for 3,000 miles without stopping.

Unfortunately, no country outside of Germany has large dirigibles for use for this purpose. Had we got them they could be used to patrol the ship lanes daily. No submarine would be safe, no matter where at sea, with large dirigibles patrolling, because large dirigibles carry guns of sufficient calibre to sink a submarine with a single shot. Likewise, the observers from a dirigible, as in the case of an observer from an aeroplane, can see a submarine miles away, when a man from a ship cannot see it, and as the airship travels many times faster than the submarine and the submarine could not easily detect the approach of the airship, the submarine would stand no chance.

Unfortunately, the Allies are far from being in a position to patrol the sea lanes with a large number of airships, although there is a possibility that Great Britain will put some into service within a few months.

The submarine menace can be checked by present-day aircraft—seaplanes, small dirigibles and kite balloons. We are now building large seaplanes which are capable of carrying fuel for continuous flights of over fifteen hours and capable of going at a speed of over seventy-five miles an hour. American manufacturers have supplied quite a number of large seaplanes of this type to England, and, as Mr. C. G. Grey, the editor of the "London Aeroplane," has pointed out, "If America is seriously perturbed about the fate of American shipping and American citizens traveling by sea, it should not be a difficult matter for America to rig up in a very short space of time quite a fleet of aeroplane carriers suitable for handling these big seaplanes."

What different types of aircraft can do in hunting submarines is told in the advance page proofs of a chapter from the forthcoming text-book on Naval Aeronautics by Henry Woodhouse, being published by the Century Cmpany, of New York, which is extensively illustrated.

THE NEWS OF THE WEEK

Aeronautic Legislation in Appropriation Bill

The Army Appropriation bill, H.R. 13, contains the following provisions of new law:

Aviation—Not more than $10,800,000 of foregoing appropriation ($11,800,000, Signal Service) shall be used for the equipment of buildings, supplies and expenses of the Aviation Section, and for paying officers and enlisted men of the Reserve Corps of the Aviation Section called into active service, development of a suitable type of aviation motor, and for investigations to be made by and technical instruction of commissioned and non-commissioned officers of said section.

Hereafter motor-propelled vehicles, aeroplanes, engines and parts thereof may be exchanged in part payment for new equipment.

The Secretary of War is authorized to acquire, by purchase, donation, or by condemnation, such land sites throughout the United States as are immediately necessary for permanent establishment of aviation schools, aviation posts, and experimental aviation stations and proving grounds for the Army.

In order to carry this legislation into effect the Secretary of War is authorized to use portion necessary of $13,281,666 appropriated for Signal Service in Army Act of Aug. 29, 1916, provided that not more than $4,500,000 shall be made available for this purpose. The funds thus authorized for purchase of land sites may also be used for improvement and preparation of land and waters contiguous thereto; for construction, maintenance and repair of buildings and for equipment and supplies. The funds thus authorized to be available until expended; not more than $600,000 of foregoing sum shall be used for purchase of land; no part of foregoing appropriation shall be expended for purchase of aviation fields if it is found practicable to lease suitable tracts for such purposes on more favorable terms.

Hereafter nothing in Sec. 25, National Defense Act of June 3, 1916, shall be held to prevent detail of an officer in Aviation Section of Signal Corps.

Mileage to officers in Aviation Section, Signal Corps, traveling on duty in connection with aviation service shall be paid from appropriation for work in connection with which travel is performed.

Specifications for Military Pursuit Aeroplanes Issued

The Aviation Section, Signal Corps, U. S. Army, has issued specification No. 1003 covering military pursuit aeroplanes. Hitherto AERIAL AGE has presented the aeronautic specifications in full to its readers, but in view of the possibility of transferring information to the enemy, we merely announce the issuance of these specifications, with the suggestion that manufacturers interested may obtain copies from the Officer in Charge of Aviation, Signal Corps, War Department, Washington, D. C.

Aero Section for Fourth Battalion Naval Militia

J. B. R. Verplanck is co-operating with the officer commanding the Fourth Battalion of the N. Y. Naval Militia and is in charge of the Aeronautic Division. The division has already secured its full complement of men, and it is expected that the mustering in services will be held in the very near future, after which the men will be sent to a navy aeronautic station for training.

In securing the services of Mr. Verplanck, the unit will have advantage of his vast amount of flying experience, and under his guidance rapid progress should be made with the tuition.

630 New S. A. E. Members

New York.—The new membership campaign of the Society of Automotive Engineers is gradually reaching the 1,000 mark, its goal. To date 630 applications for membership have been received, of which forty-one were received this week. The list has jumped from 484 in one week, an increase of practically 200. Should this rate of increase be kept up or bettered, it is possible that the 1,000 mark will be reached by the end of May.

Beverly Farms Citizens Give Beach to Uncle Sam

Boston—The West Beach Corporation, composed of all the citizens of Beverly Farms, turned over West Beach, one of the most exclusive bathing beaches on the North shore, to the government for aviation purposes. Lt. F. F. Lincoln took charge of the property, which includes a long pier and a well-furnished pavilion, with locker rooms and other conveniences. The grounds will probably be used for the naval reserve aviation school.

Mystery Island, which was the site of last year's naval militia aviation school, will undoubtedly be taken over entire this year in connection with the West Beach camp.

Efficiency of American Motors

A very interesting statement concerning the life of an American aeronautic motor, comes from N. B. Robbins, an aeronautical engineer at North Island, California. Mr. Robbins writes:

"The motor I refer to is in machine No. 157-Curtiss Jn used for training by myself. It has now run officially 127 hours. Is now in perfect working order. Turns the propeller now at 1425 r. p. m. I believe I would be safe in saying the average is about 1400 for the type and size engine. Sometime ago a congressional committee visited the school here and we flew in review with about 20 machines. On this trip I piloted my machine without student, and I attained an altitude of 3,700 feet in just seven minutes, this with the motor I speak of and at that time had run about 100 hours. I know that this as above the average. I hope to be able to get 150-175 hrs. from this motor, and from indications it will easily do it. It is some pleasure to train in a machine that is always on the job."

Members of Instructor Vernon's Class Hold Banquet

Memphis—Members of Victor Vernon's class at the United States Aviation Station at the North Memphis Driving Park recently gave a dinner at Hotel Gayoso. Those present were the men who have been turned loose, as the aviators say, after instruction under Mr. Vernon. All are Chicagoans.

Those present were Harry W. Powers, William J. Seleck, R. W. Schroeder, A. E. Wolf, Frank W. Alsip, Victor Vernon, Charles W. Browne, Geo. F. Fisher, Andrew C. Ortmayer and Jack Foote.

New Wright-Martin Stock

New York City.—Stockholders of the Wright-Martin Aircraft Corp. will be asked shortly to approve an increase in the authorized amount of capital stock from 500,000 shares to 1,000,000 shares of no par value. There are now outstanding 400,000 shares, 350,000 having been issued at the time of the company's organization, while 50,000 were sold recently to provide for current payroll expenses. It was announced yesterday that the new issue of 500,000 shares will be underwritten by the interests who organized the company, without commission. The stock, it is understood, will be offered to shareholders at the underwriting price, which may be $5 a share. The new financing will provide the company with approximately $2,500,000 working capital.

Miss Ruth Law in aviator's costume of the U. S. Army. Miss Law is doing excellent recruiting work in Chicago

Aerial Coast Patrol Unit No. 3 Take Oath

The members of the Aerial Coast Patrol Unit No. 3, organized by Clinton D. Backus, a Yale student, took the Federal oath yesterday and were enrolled in the United States Navy. They started training immediately on the estate of J. P. Knapp at Mastic, L. I. The men of the unit are Clinton D. Backus, organizer; Harold Pumpelly, William Connors, Leslie MacNaughton, Joseph Nagel, Harold Howe, Thomas Dixon, Jr., Duncan Forbes, Jack Mitchell, David Dunlap, Edward Thurston and Hamilton Gardner.

Tender Plant to Navy

Seattle, Wash.—Arthur Wesley Davis, the aviator, has formally tendered his aviation plant at Bellingham and his personal services to the Navy Department, and they have been accepted.

Davis is now awaiting further orders. The advice from the Bureau of Accounts and Construction, to which department his offer was referred, arrived last week. The aviation expert is notified to hold himself and his plant in readiness for further instruction.

Several years ago Davis became an aviation enthusiast and attached himself to the Curtiss School at San Diego. After graduating as an aviator, he became an instructor, and served a short time as assistant trainer at the Curtiss establishment.

Westport Needs Money for Aviation Camp

Westport, Conn.—The men behind the recently organized Aviation Camp at Westport have sent out a call for $75,000 for the purpose of carrying out the plan. Their estimate follows:

"To equip a station at Westport will require $75,000. It will cost $22,000 to buy two training machines; $24,000 for the purchase of a real war machine (a hydro-aeroplane mounted with rapid fire guns and the bomb dropping device); one twin screw speed boat for the picking up of aviators who fall into the water, a very necessary part of the equipment of a training camp, at a probable cost of $8,000. It will be necessary to have three extra motors, one motor tow boat, spare parts, tools and equipment, motor truck and motorcycle."

Captain on Aerial Duty

Washington, D. C.—Captain Clarence C. Culver, of the cavalry, was ordered last week to make three trips to Hampton, Va., this month to assist in radio and photographic work with aeroplanes there.

He will assist recruits in use of wireless while flying, and also in use of the telescopic photographic apparatus now commonly applied in aeronautic operations.

Many of the recruits are being trained to air fighting by using the so-called camera rifle. It is a photographic device in which an aviator aiming at another machine pulls the trigger of the apparatus, but instead of firing a shot registers a picture. If the picture of his opponent occurs in the resultant negative, that is equivalent to a "hit."

First Aeroplane Reaches Wheeling

Wheeling, W. Va.—The first aeroplane for the recently organized West Virginia Flying Corps, now established at Beech Bottom, was shipped to Wheeling last week. It will be transported to the training ground at Beech Bottom the first of this week and will be fitted up immediately for use.

Louis Bennett, Jr., organizer of the corps, arrived here from the East, bringing with him F. G. Wegerhauser, Tacoma, Wash.; Nelson Hawkes and T. T. Kent, of California, which will be pupils at the training field.

Two Students in Fatal Accident

Mineola: An escapade in which two mechanics deliberately disobeyed orders by taking into the air one of the instruction machines at Mineola, ended disastrously on May 7, when Private Ransome H. Merritt, and Private Anthony P. Spilener were killed. The two young men, overambitious about acquiring a knowledge of aeroplane handling, took advantage of the fact that they had been ordered to prepare one of the L-W-F biplanes for the day's instruction. Without permission they took the machine into the air and after a half hour's thrilling gyrations one of the wings collapsed and the machine crashed to earth, killing both of the occupants.

Army and Navy News

Major Tulasne and Lieutenant de la Grange, two French army aviators, have reported to General Squier with a view to offering their services in the work of building up the American aviation service. The visiting officers have been assigned desks in the office of the C.S.O. and were in daily conference with him.

Authority has been given for the organization of the 1st and 2d Reserve Aero Squadrons at New York City and Philadelphia, respectively. The commanding general of the Eastern Department was instructed to complete these units by the assignment of officers and enlisted men from the Aviation Section, S.R.C.

Each of the following officers is detailed in Aviation Section of Signal Corps and is rated as a junior military aviator: First Lieuts. William O. Ryan, Cav.; Charles C. Benedict, Jr., Inf.; Harold P. Cousins, Cav.; George E. Stratemeyer, Inf., and Melchior McE. Eberts, Inf. (May 3, War D.)

Capt. Harold S. Martin, junior military aviator, S.C., from duty at Mineola, Long Island, N. Y., to Washington, D. C., office of Chief Signal Officer, for duty. (May 2, War D.)

First Lieut. John G. Colgan, Aviation Section, S.O.R.C., to active duty at Fort Sam Houston, Texas. (May 4, War D.)

Sergt. 1st Class Fred J. Scheidegger, 1st Aero Squadron, S.C., Columbus, N. M., to 3d Aero Squadron, S.C., Fort Sam Houston, Texas, for duty. (April 14, S.D.)

Aviation School for Northampton

Bethlehem, Pa.—At a meeting at the Easton Board of Trade rooms, the Northampton County Aviation Club was organized, with T. A. H. Hay as president and George M. Shook, as secretary. It is proposed to purchase one or more aeroplanes for the use of young men of the county who care to learn to fly. It is likely that the landing place will be the grounds of the Northampton Country Club.

Personal Par

Miss Helen Birkett, daughter of Mr. and Mrs. Clarence T. Birkett, of No. 540 West 122d street, joined the list of war brides May 12. The bridegroom was Torrey H. Webb, young mining engineer, who has just completed a course at the Army Aviation School, at Mineola, L. I. He received orders May 12 to report next day at the aviation station at Newport News, Va.

Aviation Card Party in Brooklyn

On May 7th, Miss Katherine Glidden gave a bridge party at the Hotel St. George for the purpose of raising money "For making the new group of airmen that, to the number of thousands, promise to become important figures of defense in all war conduct in the near future."

Mr. Augustus Post, of the Aero Club of America, gave a very interesting talk upon aviation, and especially on the side of aircraft as a defense against submarines.

Athletes in Aviation Section

Philadelphia.—Two of old Penn's most noted athletes, Ted Meredith and Howard Berry, have gone to Washington to file their papers for the United States Army Aviation Corps. Meredith is probably the greatest of all half and quarter mile runners, and Berry is certainly one of the greatest all around athletes in the history of sport. Meredith's home was in Media, Pa., but he has been living in Philadelphia, while Berry is a resident of this city.

J. B. R. Verplanck, who is in charge of the recently organized aero unit of the Fourth Battalion, Naval Militia

Hotel With Aerodrome Roof

A landing station for aeroplanes is the latest proposal being considered for the Hotel Commonwealth, which is shortly to be built in the Times Square district of New York. The announcement is the more interesting because it carries with it the recognition of the rapidly increasing importance of flying as a mode of travel, and the general belief is that there will be a great demand for such landing stations. The roof of the Commonwealth—which is to be the greatest hotel in the world—will offer excellent facilities for such a purpose, both from the standpoint of size and location.

Standing 28 stories high, the great hostelry will stretch across an entire block-front and will contain 2,500 rooms.

The entire Commonwealth enterprise is unique. The plan is co-operative, the hotel is to be owned and operated by something like 100,000 shareholders, holding from one to ten shares of stock each, at a par value of $100. No one will be allowed to subscribe for more than ten shares. Thus an army of men and women representing every section of the country will be regular patrons of the Commonwealth.

The Hotel Commonwealth will merge hotel and club life, so that the shareholder may enjoy during his stay in the city, the use of gymnasium, swimming-pool, reading, smoking and lounging rooms, indoor golf, tennis, squash and other club luxuries.

Cylinders and Crankshaft Rotate in New Engine

Chicago.—An aviation engine in which cylinders and crankshaft both are permitted to rotate has been developed here by the Muffley Motors Co. and the design is such that it has aroused interest in governmental circles. It is known as the Muffley engine, and at present is designed for ten cylinders approximately 4½ by 5⅛ in. The engine as a whole is similar to the present rotating cylinder engines, such as the Gnome, except that not only do the cylinders rotate, but that the crankshaft rotates in the opposite direction, each at a speed of approximately 1,200 r.p.m. The relative speed therefore is 2,400 r.p.m. The valve action is almost the same as that used on the old Adams-Farwell engine, Glen Muffley, the designer of the new engine, having been instrumental in the design of the earlier motor.

For aviation work two propellers are to be used, one operated by the crankshaft direct, and the other by the cylinders direct, the propellers being of opposite pitch and one behind the other, rotating in opposite directions. Muffley claims that the efficiency is higher than that of two propellers side by side, and very much higher than that of a single propeller. The use of two oppositely rotating propellers in this way is not new, as Captain Baldwin employed this arrangement many years ago in one of his dirigibles. The double rotation engine is also not a new idea, the Root motor, patented in England about 1912, being precisely similar in scheme.

One of the assembly rooms of the Hall-Scott Motor Co., at San Francisco

In Interest of Aeronautics

Friends of Mr. and Mrs. Jonathan Butler, of No. 600 Park avenue, who are especially interested in the aviation cause being fostered by the Aviation Committee of the National Special Aid Society met at the home of Mr. and Mrs. Butler on April 22. Mrs. William Allen Bartlett, chairman of the society, presided.

Those who spoke were Cosmo Hamilton, who has seen anti-aircraft service in the British army; Henry A. Wise Wood and Irvin S. Cobb. Augustus Post discussed the technical side of aviation, and lighter entertainment was given by Miss Janet Beecher, who recited, and Miss Tyson Page, who sang patriotic songs.

Closer Co-operation Between the Hess-Bright and S K F Ball Bearing Companies

In line with plans made last autumn when certain New York interests, including the National City Bank and Messrs. Brown Bros., Bankers, of New York, who were previously interested in the S K F Ball Bearing Co., also acquired an interest in the Hess-Bright Manufacturing Co., of Philadelphia, it is now announced that plans have been perfected for a closer co-operation between these two leading concerns in the ball bearing industry.

The affairs of the two companies will be administered by a recently formed New York corporation, the S K F Administrative Co., of 1 Wall Street. The board of this company consists of Mr. Frank A. Vanderlip, president of the National City Bank; Mr. Thatcher Brown, of Brown Bros.; Mr. F. B. Kirkbride, Mr. S. Wingquist, Mr. Axel Carlander, Mr. Marcus Wallenberg, a well-known banker of Sweden, and Mr. B. G. Prytz, who as president of the S K F Ball Bearing Co. has been active in bringing about the fusion between his company and the Hess-Bright Company. Mr. Prytz has been elected president of the Administrative Company.

Simultaneously Mr. Budd D. Gray, of the Hess-Bright Company, has resigned as president of the Philadelphia company and will become technical advisor to the new New York corporation, which will thus have the benefit of his experience in its various interests. At the board meeting of the Hess-Bright Company on May 8th, Mr. B. G. Prytz was elected to succeed Mr. Gray as president.

The S K F Administrative Company is extending the manufacturing facilities of both the Philadelphia and Hartford plants, and the demand for the company's products continues to be so far in excess of the present supply that it has been considered advisable to immediately make additions both to the S K F and Hess-Bright factories, in spite of the present building costs.

The closer co-operation between the two companies was greatly facilitated by the action of the American Hess-Bright stockholders in buying out the German minority interest in the Hess-Bright Company shortly before the break with Germany, whereby all the stock came into American hands at what is reported to have been a very favorable price for the purchasers.

Fourth and Fifth Aero Squadrons in First Provisional Army Corps, U. S. Army

Major General John J. Pershing, U. S. A., commanding the Southern Department, in which the greater bulk of the U. S. Army is now stationed, has issued important general orders, organizing the troops under his command on a war basis, to be known as the First Provisional Army Corps. The following sections relate to the Aviation Corps:

Departmental Organization.—(The Aviation Department staff officer is yet to be designated.)

Technical and Administrative Staff.—Aviation Officer, Major T. F. Dodd, S.C.

Troops.—Fourth and Fifth Aero Squadrons.

Shops.—At Fort Sam Houston, Texas. Aviation Shops.

Joins Aviation Corps

Jacksonville, Fla.—Walter Hawkins, Jr., son of Walter Hawkins, of this city, who has joined the aviation corps of the U. S. Army, is said to be one of the youngest men who has responded to the call of duty from this city in his respective branch. He is now located at Fort Scriven, near Savannah, where he is being given preliminary training with the other volunteers from this city and the Southern section.

Captain Willoughby Anxious to Serve U. S.

The Navy Department has refused to waive the age limit of 30 years for admission into the flying corps in the case of Captain H. L. Willoughby, and Captain Willoughby will return to Philadelphia after having spent two weeks or more undergoing the severe physical examination for the corps, and upon passing it in trying to secure a waiver.

Sperry Invents Device for Destroying Submarines

Washington.—The New York Sun correspondent despatched a special story May 9th stating that he had learned on "unquestionable authority" that the Naval Consulting Board has submitted to Secretary Daniels and his advisors a definite and completed plan to cope with the German U-boats which has proved a revelation to the best technical brains in the service here.

Strict censorship necessarily bars discussion of any of the technical features of the plan, but it is within bounds to make the following announcement, which should be of the greatest interest to the British and French commissions here as well as to the general public.

The plan is based on a novel anti-submarine device or invention which is theoretically sound and which is a radical departure from any invention put into operation or heretofore thought of.

Elmer A. Sperry, inventor of the gyroscope compass and one of the leading inventive geniuses in the United States navy, is the inventor.

Within two or three weeks the Navy Department will have completed practical tests of the invention under the guidance of naval officers from various technical branches in the service which will show definitely whether or not there is any unforeseen obstacle in the way of putting the invention to use.

The invention is of such a character that it can be put into operation in the war zone almost immediately. It requires no elaborate preparation or construction work, but can be made a factor in the campaign against the U-boat this summer.

Aeroplanes with Pershing Traveled 251,000 Miles

The report of the duration and distance traversed by the aeroplanes with General Pershing in Mexico, has just been made public.

From July 1 to December 31, 1916, the machines of this unit carried mail on one trip in each direction between Colonia Dublan, Mexico, and Columbus, New Mexico, without missing a trip. The average time for this 110 miles was 66 minutes, and the machines were forced to rise to an altitude of 4,100 feet above Columbus and 8,200 feet above sea level. The total flights for this unit from January 1 to December 26 were 7,087. The machines were in the air for a total of 3,356 hours, and traveled a total of 251,775 miles. The fatalities were none.

Aviation Station for Springfield

Springfield, O.—Designation by the War Department of Ohio State University as a training school for prospective Army aviators, with Columbus and Dayton as terminals for the flying course, and Springfield as one of the intermediate stations under the present tentative plans is expected to greatly increase local interest in the military service, particularly the aviation section.

Possibilities seen in the tentative plans for the aviation school for Ohio in establishing one of the important stations in this city has served to stimulate interest on the part of a number of patriotic and public-spirited men in tendering whatever aid the city and its citizens can to the government in the selection of suitable grounds.

Enters Balloon Camp

Holyoke, Mass.—Charles L. Hayward, son of Mr. and Mrs. L. F. Hayward of Brooklyn, but recently of Holyoke, has enlisted for service in the military balloon camp located at Stapleton, L. I. Mr. Hayward will receive his degree from Columbia University in June. He is a graduate of the Holyoke public schools and the Holyoke high school. His cousin, Philip Hayward, has entered the submarine service.

Army School Back to Chicago

Washington, D. C.—The War Department has ordered the army aviation school at Memphis transferred to Chicago, whence it was removed to the Southern city some time ago. "Climatic conditions" is assigned as the reason for the transfer, which was made on recommendation of Major-General Leonard Wood, commanding the Southeastern department of the army.

Aviators Honor Johnson

Memphis, Tenn.—Members of Al Johnson's class at the local government aviation station last week tendered him a theater party. In addition to Mr. Johnson, who is flying instructor, six were in the party which attended the Orpheum.

The men have been turned loose after instruction under Mr. Johnson. By turned loose the aviators mean that students are sufficiently advanced to make solos or flights alone. Those in the party were: Al Johnson, Student Instructor E. P. Hinds, Sergts. Thompson and Showalter, Corporal Jones and Sergt. First Class Chester.

The late Victor Carlstrom, who met with a fatal accident while flying at Newport News, on May 9th

Salt Lake City May Get Aviation Post

Salt Lake City, Utah.—With the passage of the general army bill by Congress, which confers extended power to Major-General Hugh L. Scott, Chief of Staff of the United States Army, Fort Douglas will be established as a brigade post, according to Fred C. Richmond, president of the Salt Lake Commercial Club. Mr. Richmond said that assurance was given him by Major-General Scott that immediately after the Army bill passed Congress Fort Douglas would be converted into a brigade post, and that a regiment now stationed on the border would be sent here to serve as a nucleus.

Mr. Richmond also conferred with Major-General Scott regarding the establishment of one of the Government's aviation stations in Salt Lake; the establishment of a Government warehouse here, and the advisability of having Fort Douglas utilized as a recruiting camp for the intermountain country, where recruits could receive preliminary instructions.

Major-General Scott said that he was exceedingly anxious to see Government aviation and warehouse stations established in Salt Lake, but that the present time was too premature to take definite action.

Victor Carlstrom

The news of the death of Victor Carlstrom will come as a shock to every one of his friends and admirers, and everyone interested in aeronautics in this country was an admirer. The accident, which proved instantaneously fatal, occurred at Newport News, Va., on May 9th, while Carlstrom was taking Carey E. Epes, a student, for his first instruction flight.

The cause of the accident was that owing to the need of hastening the training of the U. S. Army Reserve Corps students, every aeroplane was worked to the limit and the machine used by Carlstrom was practically worn out by continuous use.

Carlstrom was held in the highest esteem as an aviator and instructor. Alan R. Hawley, president of the Aero Club of America, flew with Carlstrom last July at the time of the aviation meet at Sheepshead Bay, when they made their memorable trip from New York to Washington.

"Victor Carlstrom," Mr. Hawley said, "was one of my close friends. I made several trips with him when Carlstrom was the pilot. He had many noble qualities, and without knowing the details I feel sure that this accident was not due to his piloting and must have been such as a skilled driver in an automobile might be subject to. He had a great 'air sense' and was a born cross country flyer, and seemed to know by a remarkable instinct the details of direction. In the last eighteen months we have figured that he had been in the air more than three thousand hours and thought as little of flying as most of us do of taking a motor trip."

Carlstrom established many American records, as follows:

Altitude, an aviator and one passenger, April 30, 1916, Curtiss tractor, 16,225 feet, at Newport News, Va.

Aviator and two passengers, April 19, 1916, Curtiss tractor, 11,180 feet, at Newport News, Va.

Cross country, distance, aviator and one passenger, May 20, 1916, Curtiss tractor, Newport News, Va., to Sheepshead Bay, N. Y., 283.02 miles.

Carlstrom received the Aero Club medal of merit which was awarded at the annual banquet of the club both last year and this year, and he was the winner of the Curtiss Marine Flying Trophy for 1916.

He also received a gold watch from the Aero Club of America for his flight from Chicago to New York, when he made the cross country distance record of 393.585 miles, which was afterward beaten by Miss Ruth Law.

Thorne Donnelley, a young Chicago sportsman, who has been learning to fly in order to join the Aerial Reserves, and has been Carlstrom's pupil, stated at the Aero Club that Carlstrom always allow him to correct his own mistakes. This, Mr. Donnelley stated, gave the student greater confidence and enabled him to learn to pilot in one-half the time that it otherwise would take.

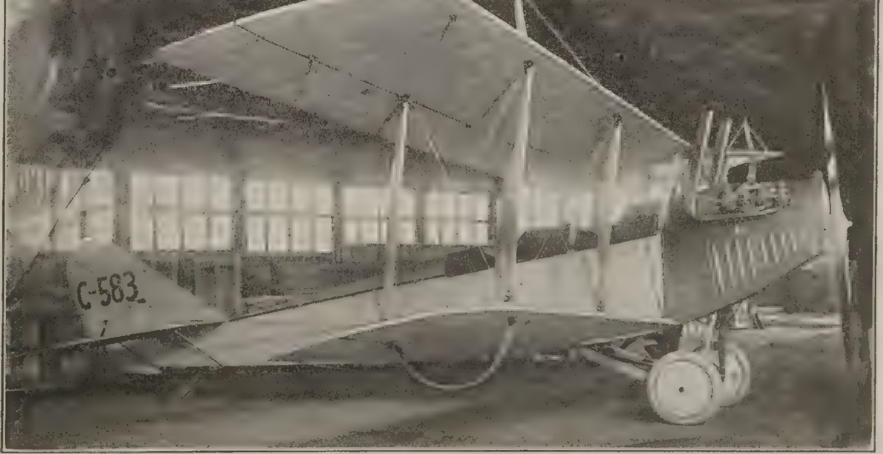
Victor Carlstrom was born on April 12, 1890, in Gustaf Fahn Lan, Sweden, and received his license as an aviator from the Aero Club of America on July 24, 1912, his license number being 144.

Personal Paragraph

L. M. Allison, formerly of the Standard Aero Corporation, has become chief engineer of the Lawson Aircraft Company of Green Bay, Wisconsin.

Fatal Accident to Naval Aviator

Pensacola, Fla.—Ensign D. R. Vankirk, U. S. N., fell 1,000 feet in an aeroplane into Pensacola Bay last week and was drowned in the wreckage of the machine.



The latest Curtiss Model JN-4 military biplane. The new arrangement of the engine exhaust pipes is noteworthy

RAPID WORK IN AERONAUTIC STANDARDIZATION

F. S. DUESENBERG read the report of the Aeronautic Division. In the discussion it was brought out that the Stick control is largely favored for light machines and the Deperdussin control, commonly known as the Dep, is favored for heavier machines. It was also mentioned that standard sizes of engine bed timbers of 12, 14 and 16 in. would also be desirable.

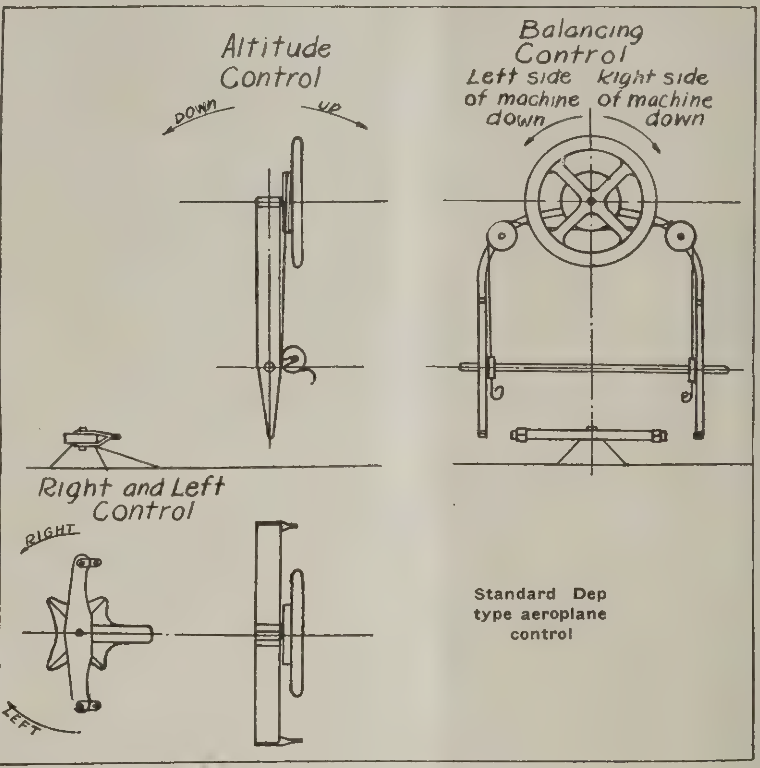
Probably one of the most important steps in view of the formative condition of the aeronautic industry was the decision to adopt the English or inch system of measurement because of the requirements of the United States Army and Navy service.

A letter was read from R. S. Griffin, engineer in chief of the United States Navy Bureau in Washington, in which he stated that the following suggested standards taken from the report are acceptable to the navy department:

1—English system of measurement.
2—Marking oil and fuel lines.
3—Elimination of gage numbers.
4—Engine supports.
5—Spark plugs.

He also suggested that a rubber tube be used to connect the gasoline tank to the carbureter and the Bureau has asked for specimens of the wire and turnbuckle fittings described in the report. In other words, the bureau is still questioning the wire tensile strengths, thimbles, turnbuckles and tachometer shaft drive.

Controls—It is found that these two types of control, namely, the Deperdussin (Dep) and Stick controls are necessary to cover most types of plane in military use. The standards specify that particular movements produce particular effects, but do not specify the connections, since these vary a great deal in practice.



Standard Dep type aeroplane control

Details for Planes

Hard Wire Loop—This consists of an oval coil of wire through which the hard wire is slipped, bent in the form of a loop, again inserted, and the end bent over against the coil. The whole is then soldered. This is identical with the present British standard.

Flexible Cable Ends—The sketch shows the cable end wrapped around a "standard thimble." The length of splice from pointed end of opening in thimble was represented by "splice plus or minus ⅛ in." The end of the splice is wrapped with a serving of shellacked harness thread. Dimension *A* represents the distance from end of opening in thimble to end of serving.

Diameter of Cable	Length of Splice	Number of Tucks	Length of Serving	A	Full Strength of Cable
3/32 7 x 14	1¼		1	½	800
⅛ 7 x 19	1½	3 over	1	½	2000
5/32 7 x 19	1¾	core buried	1¼	½	2800
3/16 7 x 19	1⅞	4 under	1¼	¾	4200
7/32 7 x 19	2⅝		1¼	¾	5600

Galvanized Non-Flexible Ends—The cable end is wrapped about a thimble, with a total length of splice indicated by *L;* 0.041 in. soft steel wire is to be used for wrapping, and the sketch indicates two spaces left between convolutions of the wrapping wire, width of the spaces being indicated in the table. The accompanying table gives the sizes and strengths:

Diameter of Cable	L	Space	Wind	Full Strength of Cable
1/16 1 x 19	1½	⅛	1	500
3/32 1 x 19	2	⅛	1¼	1100
⅛ 1 x 19	2½	⅛	1½	2100
5/32 1 x 19	2¾	⅛	2	3200
3/16 1 x 19	3	3/16	2¼	4600
7/32 1 x 19	3½	3/16	2¼	6100
¼ 1 x 19	4	¼	2½	8000

Thimbles—It was voted to approve, subject to approval by the departments of War or Navy, thimbles for wire ends as shown by Plate No. 7 following page 118, First Annual Report of the National Advisory Committee for Aeronautics (1915). These thimbles will be shown by appropriate drawings. The sizes are indicated roughly by the following table:

Size of Rope	Thickness of Thimble	Width of Eye	Length of Eye
1/16-3/32	0.075	0.35	0.70
⅛	0.12	0.35	0.70
5/32	0.17	0.40	0.80
3/16	0.21	0.50	1.00
7/32	0.24	0.60	1.20
¼	0.27	0.70	1.40
9/32	0.30	0.80	1.60
5/16	0.33	0.90	1.80
⅜	0.39	1.00	2.00

Turnbuckles—Detail dimensions of both short and long types are being studied by a subdivision consisting of Chairman Manly and Capt. Clark. The following main dimensions are recommended for immediate adoption:
(With either two eye ends or one eye and one yoke end.)

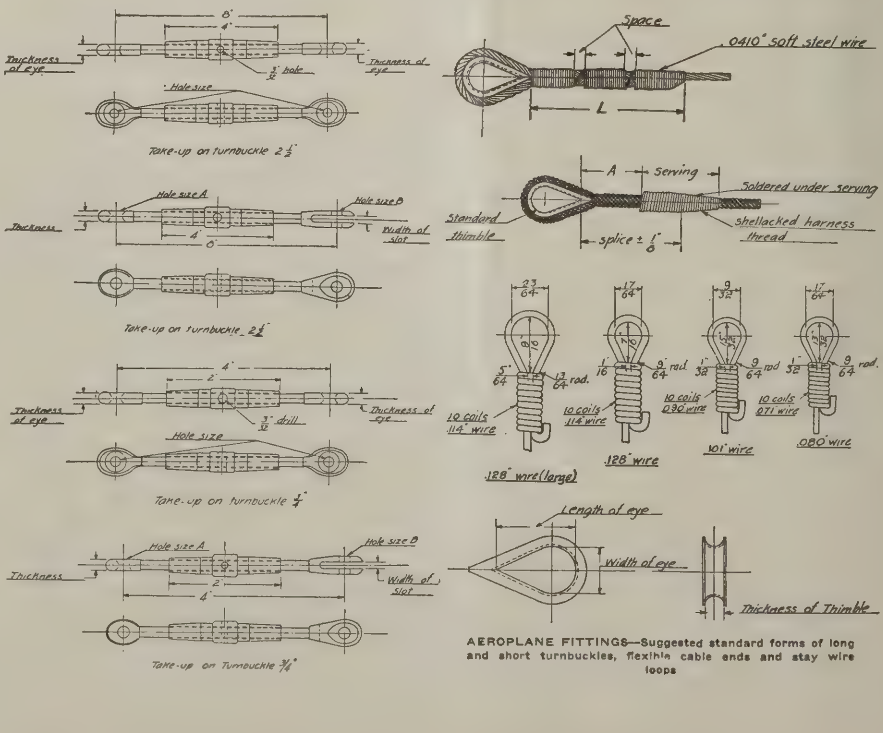
	Short	Long
Length of Barrel	2	4
Length between eyes:		
With threads flush with ends of barrel	4	8
With maximum extended	4-3/16	8-3/16
With minimum extended	3¼	5½

Strength (Lbs.)

S. A. E. Numbers	Short	Long
1	500	500
2	1000	1000
3	1500	1500
4	2000	2000
5	2500	2500
6	3000	3000
7	3500	3500
8	....	4000
9	....	4500
10	....	5000
11	....	6000
12	....	7000
13	....	8000
14	....	9000
15	....	10,000

Marking Pipe Lines—Gasoline lines should be marked with red stripes ½ in. wide painted around the pipes 24 in. apart, care being observed that there is a stripe near each end of the pipe.

The oil lines to be marked similarly but with white stripes.



AEROPLANE FITTINGS—Suggested standard forms of long and short turnbuckles, flexible cable ends and stay wire loops

Elimination of Gage Numbers—Sheet metal is to be specified by thickness in decimal fractions of an inch. Rods, wires and cables are to be specified by diameter in decimal fractions of an inch. Tubes are to be specified by outside diameter in inches or fractions and thickness of wall in decimal fractions of an inch.

Engine Supports—The division recommends the following table of dimensions, omitting all reference to sizes of bolts:

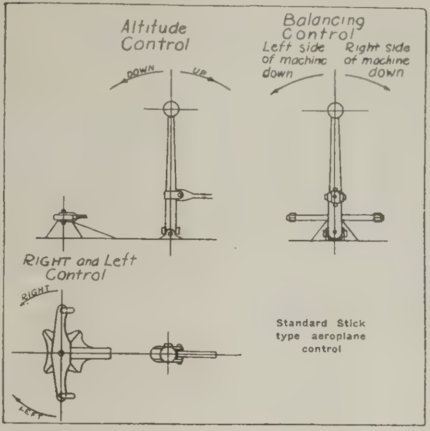
Distance between timbers...	12	14	16
Width of bed timbers......	2	2¼	2½
Distance between centers of bolts	14	16¼	18½

Basic System of Measurements—In view of the fact that the Army and Navy Departments are not both in favor of adopting the metric system, and further in view of the necessity of arriving at standards that will mean the least possibly delay in the production of aeroplane parts, this division recommends definitely to use the English system of measurement except in isolated cases such as spark-plug threads where the metric system is desirable in order to effect interchangeability with some well established standard.

Spark Plug Dimensions—The following dimensions for spark plugs were agreed upon:

Thread: 18 mm., 1½ mm. pitch.

Form of thread: International standard (Same as U. S. standard only with one-half as much truncation at root of thread).



Standard Stick type aeroplane control

Gasket shoulder to end of shell: ⅝ in.

Hexagon: 1 in. across flats.

The question of thread tolerances was deferred.

Propeller Hubs—The design of propeller hubs of various sizes should be based upon pounds-feet torque and not on horsepower.

Direction of Engine Rotation—The direction of engine rotation is normal when the final power delivery member of the engine rotates anti-clockwise, viewed facing the power delivery end. Opposite rotation is anti-normal.

Approval of Existing S. A. E. Standards—The following list of existing S. A. E. standards was approved for aeronautic practice:

Screws and Bolts: (A committee has been appointed to recommend supplemental standards.) Heat treatments; test specimens; ball bearing sizes; throttle levers; magneto dimensions, and cotter pin sizes.

Aeronautic Work Still in Progress

A sub-division consisting of Messers. Vincent, Crane and King has been appointed to take up the subject of pipe fittings. Data are also being collected regarding high grade alloy steel tubing. Some revision of the propeller shaft end dimensions is under consideration. Prof. Z. Jefferies, Aluminum Castings Co., and K. W. Zimmerschied, chairman of the iron and steel division, have been requested to submit suggestions in regard to aluminum alloy specifications.

Referred Back to Division

Three recommendations contained in the report were referred back to the division. The first of these suggested certain standard sizes for tires and rims; the second was a suggested standard design for a tachometer driveshaft, and the third was an acceptance for aeronautic work of the existing iron and steel standard specifications.

(*Continued on page* 334)

REQUIREMENTS FOR SERVICE IN ENLISTED RESERVE CORPS, AVIATION SECTION

(*Continued from page* 295)

Par.
Qualifications; general requirements...... 14
Numbers in each grade.................. 15
Qualifications for direct enlistment into each grade 16
  Master signal electricians........ 16(a)
  Sergeants, first class............ 16(b)
  Sergeants and corporals......... 16(c)
  Privates first class.............. 16(d)
  Privates .... 16(e)
Examination, master signal electricians and sergeants, first class................ 17
Certificates of enlistment............... 18
Rates of pay.......................... 19
Retirement 20
Uniform 21
Term of enlistment..................... 22

14. Qualifications—general requirements.—Service in the Enlisted Reserve Corps, aviation section, Signal Corps, is by enlistment. Applicants must be over 18 and under 45 years of age. They must be of good antecedents and habits and free from bodily defects and diseases. They must be citizens of the United States or have made legal declaration of their intention to become citizens of the United States and be able to speak, read, and write the English language. Before enlisting they are required to pass physical examination to determine their fitness for service in the United States Army. Before authority for enlistment is granted, applicants will furnish two or more certificates of good moral character. As the service is technical, men qualified as aviators, balloonists, or mechanicians, who have had experience in the construction and repair of aeroplanes or internal-combustion engines are particularly desirable.

15. Numbers in each grade.—Following are the numbers authorized in each grade:

(1) 40 master signal electricians.
(2) 140 sergeants, first class.
(3) 200 sergeants.
(4) 400 corporals.
(5) 305 privates, first class.
(6) 915 privates.

2,000 total.

16. Qualifications for direct enlistment into each grade.—Qualifications for enlistment direct into each of these grades are as follows:

(a) *Master signal electricians.*—The candidate must have a practical knowledge of gasoline motors, magnetos, carburetors, telegraphy, and a fair knowledge of the principles of electricity and photography or aeroplanes and balloons.

(b) *Sergeants, first class.*—The candidate must have a working knowledge of gasoline motors, magnetos, carburetors, and a fair knowledge of the principles of metal working.

(c) *Sergeants and corporals.*—Candidates must have a general knowledge of the subjects given under requirements for first-class sergeants.

(d) *Privates, first class.*—Applicants must show an interest in the subjects mentioned, be competent, keen, and of a sufficiently high order of intelligence to insure that they will develop along the proper lines in training.

SECTION IV.

(e) *Privates.*—Applicants must possess the physical, mental, and moral qualifications necessary for enlistment in the Regular Army.

17. Examination, master signal electricians and sergeants, first class.—Candidates for enlistment as master signal electricians and sergeants first class, may be given a written examination embodying the subjects mentioned above.

18. Certificates of enlistment.—When men enlist in any of the above grades, certificates of enlistment in the aviation section, Signal Enlisted Reserve Corps will be issued by The Adjutant General of the Army. When called into active service or when called for purposes of instruction and training, the holders of certificates of enlistment will possess all the authority, rights, and privileges of like grades of the Regular Army during the period of such active service, instruction, or training. Members of the aviation section, Signal Enlisted Reserve Corps, shall take precedence in each grade of said corps according to dates of their certificates of enlistment therein. When called into active service, or for purposes of instruction and training, they shall take precedence next below all other enlisted men of like grades in the Regular Army. The President is authorized by law to assign members of the aviation section, Signal Enlisted Reserve Corps, as reserves to particular organizations of the Regular Army. The Secretary of War is authorized by law to order enlisted men of the aviation section, Signal Enlisted Reserve Corps, to active service for purposes of instruction or training for periods not to exceed 15 days per year, provided that, with the consent of such enlisted men and within the limits of funds available for these purposes, the periods of active service may be extended for such number of enlisted men as may be deemed necessary. During such periods of active service, instruction, or training, and including the time required for actual travel from their homes to the places to which ordered and for return to their homes, enlisted men will receive the pay and allowances of corresponding grades in the Regular Army.

19. Rates of pay.—The grades and pay of the enlisted force of the aviation section, Signal Corps, United States Army, are as follows:

	While serving in the United States, Hawaii, Porto Rico, or the Canal Zone. *Per mo.*	While serving in Alaska, China, or the Philippines. *Per mo.*
Master signal electricians.....	$75.00	$90.00
Sergeants, first-class	45.00	54.00
Sergeants	36.00	43.20
Cooks	30.00	36.00
Corporals	24.00	28.80
Privates, first-class...........	18.00	21.60
Privates	15.00	18.00

All enlisted men of the aviation section, Signal Corps, of the United States Army, in addition to their regular pay, receive rations, quarters, clothing, fuel, bedding, medicine, and medical attendance when required.

20. Retirement.—Enlisted men of the aviation section, Signal Enlisted Reserve Corps, will not be entitled to retirement or to retired pay, nor will they be entitled to pension except in case of physical disability incurred while on active service or while traveling under orders of competent authority to or from designated places of duty.

21. Uniform.—The uniform to be worn by the enlisted men of the aviation section, Signal Enlisted Reserve Corps, except corps insignia, shall be the same as prescribed for enlisted men of the aviation section, Signal Corps of the Regular Army Reserve. In time of peace there shall be issued to each enlisted man of the aviation section, Signal Enlisted Reserve Corps, such articles of clothing and equipment as may be prescribed. All clothing and equipment shall remain the property of the United States.

22. Term of enlistment.—The term of enlistment is four years.

SECTION V.
CIVILIAN AERONAUTICAL SCHOOLS.

Par.
General requirements 23

23. General requirements:—

(a) *Inspection and approval by War Department.*—The civilian aeronautical schools will be those approved by the War Department as to instructors, equipment, and character of instruction to be given. They will be inspected to determine whether these requirements are fulfilled. Before assignment to a civilian school students will be subjected to an examination.

(b) *Pay for tuition.*—Each aviation school will be given a certain compensation for instruction of such personnel assigned thereto in amount to be determined upon by the War Department and the proprietor of the school for each aviation student who qualifies for the preliminary flying test. This amount will be paid when the student satisfactorily completes the course. For each aviation student who graduates from a civilian school as a reserve military aviator an additional sum, jointly to be decided upon by the War Department and the proprietor will be paid to the school. Upon qualification in the preliminary flying test a student may, at the option of the War Department, be transferred to a Government school for advanced training or be permitted to complete his training at the civilian school.

24. Aviation schools—Special requirements.

(a) *Field.*—The field should be of sufficient size and shape to permit of landing and getting away in at least two different directions under normal conditions. The ground must be fairly level and free from obstructions of all kinds. These requisites will be determined on inspection by an officer or agent of the aviation section of the Signal Corps.

(b) *Training machines.*—The training machines will comply with the specifications prescribed by the aviation section, Signal Corps, for the preliminary and advanced training types. These specifications will be furnished all civilian schools who instruct students for the Government, or desire to do so.

METHOD OF SELECTION OF AN AEROPLANE WING AS TO AREA AND SECTION

By J. A. Roché, M. E.

This phase of design, although of great importance if the highest efficiency is to be attained, has long been neglected. The first reason for this was the lack of experimental data on which comparative calculations could be based, and now that this data is plentiful and trustworthy, there is no quick and easy way to lead one to the correct combination of section and area to be used.

This difficulty arises from the fact that both section and area are functions of each other and also of the weight, power, head resistance and intended purpose of the machine.

Anyway, an aeroplane is pretty sure to fly satisfactorily providing that the relation between the above factors be chosen with "good taste" or with an eye on the neighbor's machine, but there is ever the doubt that the machine is not at its best—perhaps a different curve would be preferable—perhaps a little less surface would be better.

One of the common methods now used in making this selection consists in picking out the curve of highest lift to drift ratio available, and finding the area by means of the familiar formula:

$$S = \frac{W}{K_y V^2}$$

Where: W = the weight of the machine, fully loaded.
K_y = the highest lift coefficient
V = the low speed hoped for in m.p.hr.
S = the area sought.

It is generally assumed that the section chosen is the best; because it has the highest lift to drift ratio; but no fair test of the combination is had until the characteristic curves for the aeroplane are drawn. Moreover, to draw such curves for several combinations of section and area would require a great deal of work and then the comparison would be rather difficult.

Now I propose to demonstrate a method which I have found simple and satisfactory.

In general, the problem presents itself as follows:

Specifications require a certain climb, speed range, and useful load to be carried and we are given a power plant. There are seven variables to be considered, namely:

$$K_x, K_y, A, V, S, P, W.$$

These are related by simple expressions:

$$W = K_y S\, V^2$$

$$P = (K_x S\, V^2 + K\, A\, V^2)\, V.$$

Where K_x = The drift coefficient
A = The area of an imaginary square plate whose air resistance would be equal to that of all the structural parts of the machine, or to the parasite resistance.
K = The coefficient for $A = .00328 \dfrac{\text{lbs.}}{\text{sq.}' \times \text{M.P.H.}^2}$
P = The power available in lb. miles per hr.
V, S, W, K_y as above

From which we get by transposition and cancellation:

$$K_y = \frac{W}{S\, V^2} \text{ and } K_x = \frac{P}{S\, V^3} - \frac{K\, A}{S}$$

It now becomes necessary to apply to these equations the factors that will make them yield results in terms of the desired units and those that will compensate for the following: Aspect ratio, reduction of size and wind velocity, interference or biplane effect.

All possible care must be exercised in selecting these coefficients, they will be different for different types of machines—the following are not chosen with any type in view. Some valuable indications of these coefficients may be found in Loening's "Military Aeroplanes" and in Eiffel's books.

Mr. Eiffel recommends that the area be multiplied by 1.1 to allow for the greater efficiency of large planes moving at high speed. We can also multiply the area by 1.08 to allow for the greater efficiency of the aspect ratios commonly used. Finally K_y, being affected by interference, can be multiplied by .9, the equations thus corrected become:

$$K_y = \frac{W}{1.08 \times 1.1 \times 9 \times SV^2} = \frac{W}{1.07\, SV^2}$$

$$K_x = \frac{P}{1.1 \times 1.08 \times SV^3} - \frac{KA}{1.1 \times 1.08 \times S} = \frac{P}{1.19\, SV^3} - \frac{KA}{1.19\, S}$$

It would be more accurate to apply these corrections to the characteristic curves of the wing sections tested, however the errors of this method are slight, and since the same error is introduced in all cases, the value of this method is not impaired for purposes of comparison.

Consider the graph of these equations, K_x being plotted against K_y for various values of V and for assumed constant values of S, W, P and A.

Note that these equations give the values of K_y *necessary* to fly and the values of K_x *available* at various velocities. Note also that the effect of the second term of the K_x equation is merely to subtract a constant amount from the K_x which would be available were there no head resistance. This amount depends only on A and S and its value is read on the K_x scale of the diagram. The effect of this term is then to displace the origin of the plot to the right along the K_x axis. In order that this origin be easily located for any possible value of A, which will naturally vary according to the dimensions of the machine, and for the values of S under consideration, a set of lines is drawn as shown on lower left hand corner of wing selection diagram, from which the value of $\dfrac{K\,A}{1.19\, S}$ is projected up on the K_x scale and the origin thus located for any given conditions. Using this new origin K_y values remain as they were, but the new K_x values are those that remain to drive the wings alone through the air.

Now consider the polar curves of certain tested wing sections; these curves first devised by Mr. Eiffel seem to me by far the most ingenious method of representing the characteristics of a wing section, and I wonder why their use has not been more widely adopted in this country. Polar curves can be derived, however, from any other characteristic curves available, or translated to the desired scale of units and size from foreign polar curves.

Note that these curves give the K_x *required* by the section to move through the air at various angles and the K_y *available* with the section if it is made to travel at various incidences.

Then recalling the matter on page 4
K_x available — K_x required = K_x excess
K_y available — K_y required = K_y excess
K_x excess × AV^2 = Excess power
K_y excess × AV^2 = Excess lifting capacity, extra load which could have been carried,

or

$$\frac{K_x \text{ excess} \times 100}{K_x \text{ available}} = \% \text{ excess power}$$

$$\frac{K_y \text{ excess} \times 100}{K_y \text{ available}} = \% \text{ excess lifting capacity.}$$

These values as well as the speed ranges, can be obtained easily for several combinations of section and area by superposing polar curves and the diagram, several examples of which are given later.

It is evident that the above excesses are the horizontal and vertical intercepts between the selection curve and the polar curve and when these excesses are zero we have the limits of flight range.

We can at once proceed to illustrate the method by an example:

Let W = weight of machine complete with load—2,500 lbs.
H.P. = 120, available with variable efficiency.

Assuming various values for V we can tabulate values for K_y and K_x for values of S. Let us try 250, 350 and 450 sq. ft. Then plot the curves of K_x in function of K_y writing on the curves the velocities for which these coefficients occur. This will be our wing selection diagram.

A curve in the example is also given for 350 sq. ft. and 1,900 lbs. to stimulate empty gas tanks, in order to show the conditions of flight when the machine is light.

The peculiar waves in these curves are due to the variable efficiency assumed for the power plant. We know that this varies from zero when the machine is standing still to a maximum value when the machine is going near its highest speed, and then decreases again. If the efficiency was constant these curves would be of the simple form:

$$X = CY^{1\,1/2} + c \text{ which is a parabola}$$

The tabulation and diagram follow:

E = Assumed efficiency of power plant
$HP \times E$ = Power available

(To be continued)

THE MECHANICAL DEVELOPMENT OF AVIATION

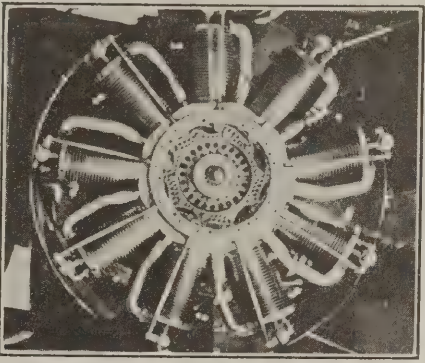
By NEIL MacCOULL, M. E.*

(Continued from page 261)

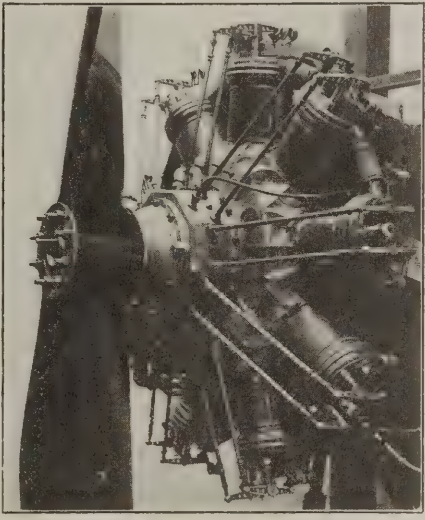
All this work of Langley's was terminated in 1903. Four years later Bleriot constructed an aeroplane of the Langley type, and was able to make short flights of a few hundred yards. The evolution of this machine resulted in the well known "Bleriot type" which is now famous in having been the first to cross the English Channel. In looking over some of my clippings a few days ago I found one from the New York Herald dated Sept 9, 1908, with large double column headlines which read: "Orville Wright Flies for 11 minutes." It brought home very vividly the extreme youth of this new science.

It is during this early period of development that the genius of inventors who were unguided by engineering knowledge went wild, and Fig. 8 is an example of the type of creation they turned out. It was described in an automobile publication in the early days, under the caption of "Why Few Airships Fly." An excerpt from the article is very interesting. It reads thus: "When every element that tends toward safety and reliability in an engine is sacrificed for light weight, the result is not apt to be sound mechanically nor in any other sense of the word. But this is in effect what the average designer of an engine for aerial navigation does, particularly when he happens to be an individual to whom the attainment of aerial navigation is everything and the engine merely an incident. But for all that, he is not content to take advantage of the principles evolved by gasoline engine designers after many years' study and practice, and must needs bring forth a genesis of internal combustion engine from the depths of his own inner consciousness. This is a four cylinder horizontal opposed, two cycle air cooled engine, without a crank-case. Initial compression is obtained by closing the inner ends of the cylinders by rectangular aluminum casings which move back and forth with the pistons. To insure sufficient cooling surface the smooth cylinders are tightly wound with a mass of woven wire, which gives them much the appearance of being sections of a mattress out of place."

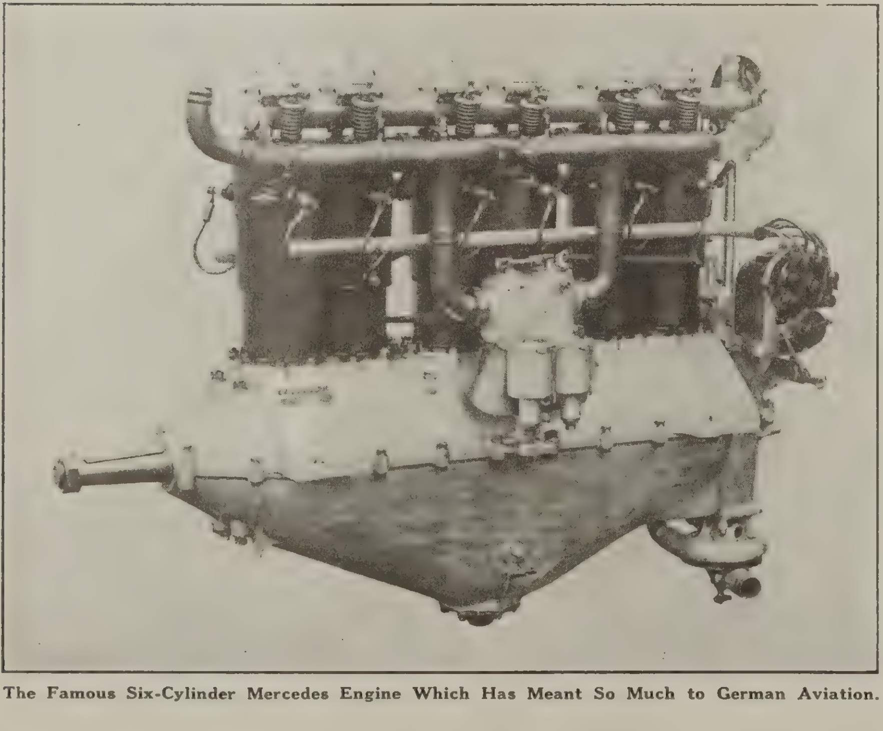
Since then progress has been very rapid. Five years elapsed from the time Langley solved the aerodynamic and mechanical details necessary for flight, before the Wright brothers succeeded in flying before the public for eleven minutes; and in 1914, only six years later, the world's record for a non-stop flight had been raised to 24 hours, and a distance of 1,500 miles. This record still stands officially, for what is done in warfare is not accurately known by the public. This is the reason that Prèvost's speed record of 126 miles an hour made in 1913 still stands as official.



The Revolving Air-cooled La Rhone Engine.



Nine-Cylinder Salmson Radial Engine.



The Famous Six-Cylinder Mercedes Engine Which Has Meant So Much to German Aviation.

But in spite of the fact that records for distance and speed have not been broken officially during the last three years, development has by no means retarded. Quite the contrary. We have been passing into that period where the aeroplane has been going through the refinements necessary for it to become an indispensable utility for the existence of nations, when they are beset by the calamities of war. It is really the beginning of the commercialization of the aeroplane. An engineer with whom I am acquainted has just returned from Europe with the most amazing accounts of the magnitude of foreign aeronautical progress. He states that there are in France to-day 70,000 men wearing the uniform of the British Flying Corps, including pilots, mechanics and other helpers. France and England together have about 14,000 licensed aviators, and Germany and Austria undoubtedly have as many. These 28,000 aviators do not include those of Russia and Italy. But even more astonishing than this is the statement made recently before the British House of Commons, that during the past two years Britain has spent $200,000,000 in aircraft. Another American engineer returning from Europe a year ago, after observing aeronautical conditions at the front for one of our automobile manufacturers interested in aviation, reported the sensations he experienced while flying several hundred miles in one of the Royal Flying Corps' giant triplanes, which had a wing spread of 135 feet, weighed just under 30,000 pounds, and was propelled by a total of more than 1,000 horsepower in four units. The whole world will be dumbfounded at the status of the aeroplane when the veil of the censor is drawn after the war.

One of the first engines to spring into prominence while aeroplane progress was being made by leaps and bounds, was the Gnome. It was an air-cooled revolving type somewhat resembling Mr. Langley's early though unsuccessful engine, and is an example of the most beautiful workmanship of which French mechanics are capable; which is one reason for the fact that even now it holds the world's altitude and speed records. It has two faults which have caused it to fall into disfavor in several branches of military service during the last two years. It has an inherently high fuel consumption, and it requires skilled attention. For powers up to about 100 horsepower, it is so much lighter than the conventional water-cooled engines, weighing less than half as much, that it will always have value in the type of aeroplane service where speed and quick climbing are prime essentials, and long flights are not desired. Such service is found in defending cities and fortifications from enemy aircraft, and it is gratifying to learn that our Army and Navy have at last purchased a good many of them from an American firm which has been manufacturing them for abroad.

The La Rhone, which is shown in Fig. 9, is another engine of similar type, though considerably improved, and is now manufactured by the Gnome Company. The intake and exhaust valves are located in the cylinder heads and are both operated by a single rocker. The rocker for each cylinder is operated by a "pull and push" rod, which in turn is given motion by the large cam shown within the crank-case, the crank-case cover, which is integral with the propeller shaft, having been removed before the photograph was taken. It will be noticed that this cam, which operates all "push and pull" rods for the nine cylinders, has five points. This is because it rotates at 9/10 engine speed and in the same direction as the cylinders. The ingenious valve driving mechanisms of many of these revolving engines make a very interesting study.

The only radial water-cooled engine which has enjoyed any degree of success since Mr. Manly's development of this type, is the Salmson, and during the first part of the war it was highly spoken of in France Fig 10 shows a nine cylinder engine rated at 120 horsepower when making 1,300 r. p. m. The valves, which are in the cylinder heads, are operated by individual cams placed side by side on the same spindle. The unusual valve springs are worthy of notice, since the object of this construction is to keep the springs away from the heat of the cylinders. All connecting rods are identical and pinned at equal distances around a collar which surrounds the crankpin bearing, no master rod being used. In order to prevent the collar from rotating about the crank-pin as a center, its position is determined by a train of three gears of equal diameter: one fixed to the collar; one to the crankcase, concentric with the shaft, and the third fixed to the crankweb, as an idler between the other two. This construction secures equal angularity for each connecting-rod, which is

not a characteristic of rods pinned to a master rod, as in the case of the Gnome and Manly.

But the great majority of modern aeroplane engines are an outgrowth of conventional automobile practice. One of the most famous engines of this type is the German Mercedes, which has had such phenomenal success that many of the latest engines follow it in general design. Fig. 11 shows the carbureter side of the particular design of this engine which first brought the name of Mercedes among the world's leaders. The most noticeable feature of the design is the method of operating the overhead valves by an overhead cam-shaft. While this general type of valve drive is now the prevailing style, it was quite an innovation when developed on the Mercedes. Notice how generally the engine follows the fundamental principles of accepted automobile practice. In fact, this very engine was used in racing automobiles, and has given their drivers many enviable records. No very great effort has been taken to make this engine especially light except in the cylinder construction. The cylinders, which are in pairs, are built up from steel by welding the individual parts together. The strong point of these engines has always been their reliability rather than absence of weight. It is interesting to read British reports on captured Mercedes engines during the early part of the war, in which much satisfaction is expressed in the fact that nothing unknown to British designers was revealed. Herein lies the secret of the just fame of the Mercedes: its designers instead of looking for radical departures from standard types, in order to save weight, were willing to apply minute attention to the development of recognized engineering principles in every infinitesimal detail.

There are a few characteristics of this engine which it is well to point out here, since they are now found on practically all aeroplane engines. One is a double carbureter for six cylinders. Surprising claims of gains in engine power are made for the use of two carbureters instead of one. Instances of over 20 per cent

KNOX 300 H. P. AIRCRAFT ENGINE PASSES U. S. NAVY TEST

AERIAL AGE is enabled this week to present the official report of the Government tests of the Knox 300 h.p. aircraft engine, which were conducted March 13th, 14th and 15th by the Department of Inspection of Engineering Materials of the United States Navy.

The tests consisted of:

First—Making a run for determining the points of a horsepower vs. revolutions curve.

Second—A run of six hours at rated load and rated speed.

Third—Motor was entirely disassembled, thoroughly inspected, measured up and reassembled.

Fourth—A run of an hour was made after reassembling.

The report states:

"The tests were conducted in the research laboratory of the Knox Motors Company, at Springfield, Mass., which is equipped with a Sprague electric dynamometer for measuring the output of the aircraft engine. It was not possible at the time of installation of this dynamometer to obtain one unit large enough for the purpose, therefore two units are used coupled in tandem, each unit having its arm the same length so that direct scale readings for torque may be made and added together without further computations.

"The gasoline used had a specific gravity of .743, or Baumé .585, and a calorific value of 18,900 b.t.u. per pound and was measured in calibrated tanks.

"The lubricating oil used was Oilzum fed by a gear pump with a capacity of 12 gallons per minute at 70 pounds pressure.

"The cooling water was contained in a large tank into which the entrance of fresh water could be regulated so as to keep the water entering the engine at a predetermined temperature. In the six-hour run 26½ per cent. of the heat units were absorbed by the water. This is about 60 per cent. of the amount generally used in automobile engines and thus allows of a much smaller radiator per horsepower.

"The motor is a twelve-cylinder of 4¾-inch bore by 7-inch stroke, rated at 300 h.p. at 1800 r.p.m., geared down to 1080 r.p.m. of propeller, and fully equipped with electric starting, total weight being 1,430 pounds. Besides the starting and lighting system, it carries a two-cycle air pump for furnishing pressure to the gasoline system and also a stub shaft is brought out for driving the generator of a wireless apparatus.

"The equipment consists of two Zenith 2-inch duplex carbureters, Delco battery type ignition, Rajah metric porcelain spark plugs, Bijur starting motor and generator. The current for ignition is taken from the battery at starting and from the generator when running.

"Forty-seven per cent. of the weight of the engine is a special aluminum alloy. The crankshaft is of chrome nickel steel carefully treated for great toughness. When each end is held on supports, the center may be deflected over two inches without a permanent set. Other parts are made of high grade alloy steels treated in the Knox plant to give the qualities required by the use of the piece. Great pains were taken to so design the engine that all parts were made in one piece as far as possible to eliminate the danger of loosening joints. The timing gears are integral with their shafts. The propeller gears are splined to the shafts with integral splines. Even the propeller shaft has no key in the taper, the hub having integral dogs which mesh with integral jaws on the shaft.

"The motor has a compression ratio of approximately 4.2 to 1, giving a cold compression at 120 r.p.m. of 75 pounds.

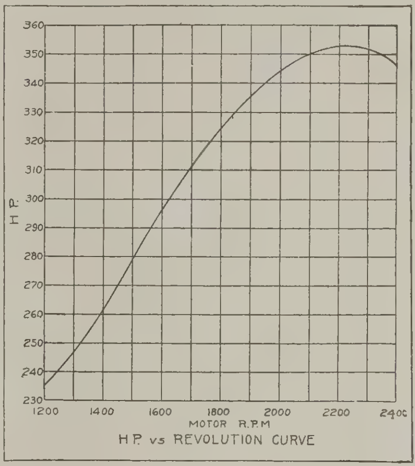
"The first test consisted in making a run with wide open throttle to obtain the points for plotting a revolution vs. horsepower curve. The speed readings were taken at three different points, viz.: the electric tachometer on the dynamometer switchboard, a revolution counter on the propeller shaft, and a second revolution counter on the motor half time shaft. The torque was measured on the dynamometer scale balance beams so that at each point the engine was run about five minutes including the greatest speed (2400 r.p.m.) at which speed the pistons have an average speed of 2800 feet per minute. At the average speed of the test the piston speed was over 2100 feet per minute, yet when the motor was disassembled for inspection after the six-hour run, no wear could be found in the pistons at the wrint pin bearings.

"The readings taken for this revolution vs. horsepower curve were:

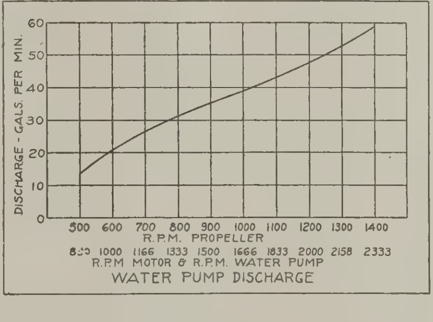
Motor R.P.M.	Propeller R.P.M.	H.P.	Torque Ft. Lbs.
1217	730	235	1685
1350	810	255.5	1655
1605	960	308	1715
1797	1086	322	1565
2039	1224	347	1485
2247	1340	353	1375
2390	1428	346.5	1265

"These readings are plotted in Fig. 1.

"The six-hour run was started at noon and readings of speed, torque, oil pressure and water inlet and outlet temperatures were taken every fifteen minuts. The day of this run the temperature in the laboratory varied from 72 at the start to a maximum of 81 and dropped to 67 near the end of the run. The day was clear, barometer reading 29.9" Hg. The gasoline used had a Baumé reading of .585 and a calorific value of 18,900 b.t.u. per pound. The readings taken during the six-hour run were as follows:



H.P. vs REVOLUTION CURVE



WATER PUMP DISCHARGE

Time H.M.	Motor R.P.M.	H.P.	Oil Pressure	Water Inlet	Temperature Outlet
00	1807	307	75	106	137
15	1820	309.5	70	102	136
30	1824	310	60	104	138
45	1815	309	60	104	138
1:00	1807	307	60	110	146
1:15	1794	305	60	106	140
1:30	1810	307.5	60	106	140
1:45	1831	311.5	60	88	129
2:00	1786	303.5	62	100	135
2:15	1793	305	68	103	137
2:30	1789	304	64	64	124
2:45	1809	307.5	62	91	133
3:00	1795	305	61	98	137
3:15	1840	312.5	60	96	134
3:30	1811	308	61	92	134
3:45	1864	317	62	100	134
4:00	1815	306.5	61	100	134
4:15	1814	308.5	62	102	136
4:30	1829	237	65	100	136
4:45	1810	287	65	100	136
5:00	1890	306.5	61	103	134
5:15	1869	304.5	60	101	135
5:30	1845	307	61	98	134
5:45	1838	304	60	98	134
6:00	1892	315	60	94	134
Average	1835	304.28	62.96	99.52	135.48

'These readings are plotted in Fig. 2.

"Shortly after four hours and fifteen minutes had elapsed, the valves between the calibrated gasoline tanks and the carbureters were accidentally closed by one of the employes who mistook these for the valves used in filling the calibrated tanks. The case of the stop was immediately located, the engine restarted, and the readings made at four hours and one-half, at which time it was noted that the resistance grids of the dynamometer set had become so hot that their resistance effect was lessened, and there was not enough load to hold 300 horsepower at the rated speed. As horsepower is a combination of speed and torque, when the torque decreases, it is necessary to increase the speed, therfore it was decided to increase the engine speed to bring the horsepower over its rated 300.

"During this six-hour run 22.45 per cent. of the heat units were converted into work, 26.5 per cent. were used in the cooling water and 51.05 per cent. used in radiation, friction, exhaust, etc.

"After this run the engine was disassembled, various parts measured for wear and careful search made for defective parts. One exhaust

DURATION OF RUN

FOREIGN NEWS

FRANCE

Paris, May 11th.—The Aero Club of France gave a dinner last night in honor of the American aviators at the front. Among the guests were Robert W. Bliss, secretary of the American Embassy; Daniel Vincent, Under Secretary of Aeronautics, and Colonel Regnier, Director of Military Aeronautics. The American Ambassador had been invited but was unable to attend.

Sergeant-Major Raoul Lufbery received from the club a gold medal, which was presented by the president, Mr. Henry Deutsch de la Meurthe, who made a brief address expressing the club's gratitude and admiration for the gallantry of the American aviators.

Paris, May 12.—A German aeroplane flew over the French front yesterday and scattered copies of President Wilson's speech printed in German which *The World* distributed originally through the French army aviators. Evidently copies had been picked up inside the German lines and were dropped within the French lines for a joke.

Hot anti-aircraft gunfire drove the German flyer back to his own lines, and French soldiers eagerly seized the leaflets as souvenirs.

GERMANY

"British and French officer prisoners of all grades began arriving to-day at the new camp established at Freiburg especially designed for officers," says a Berlin telegram of May 12.

The German government recently announced that in reprisal for the placing of a German General and fifteen staff officers on French hospital ships in the Mediterranean, French officers of corresponding rank of thrice this number had been placed "at points in the western industrial districts which are especially subject to aerial attack." Freiburg is a point which has been frequently the object of air raids.

Both the British and the French have placed German prisoners on hospital ships because of the sinking of several such vessels by German submarines.

Fighting in the air has taken on a new interest recently because of the new German policy of painting their machines grotesque patterns. They got this idea from the American Indian custom of painting their faces to frighten their opponents, or else the Spring fancies of the German airmen have been allowed to run riot.

Each day British pilots bring home new reports of fantastic creations encountered amid the clouds. The gayest feathered songsters cannot hope to rival the hues of the Harlequin birds that rise daily from German airdromes.

The coming of this order of things was first heralded by a squadron of scarlet German aeroplanes, met ten or twelve days ago. It was noticed then that some of the German machines were striped about the body like yellow-jackets.

Now there are green aeroplanes with yellow noses, silver ones with gold noses, khaki-colored ones with greenish gray wings, aeroplanes with red bodies, green wings, and yellow stripes, aeroplanes with red body and wings of green on top of blue, aeroplanes with light blue body and red wings. The gaudiest machines go in for red body effects, with every possible combination of colors on their wings. Some have one green wing and one white, while others have green wings tipped with various colors.

One of the most fantastic met had a scarlet body, brown tail, reddish-brown wings, with white Maltese crosses against a bright green background. One machine looked like a pear flying through the air. It had a pear-shaped tail and was painted ruddy brown, like ripe fruit.

GREAT BRITAIN

London, May 8.—The military correspondent of *The Times,* giving further impressions of his recent visit to the British front, replies to criticisms made of the types of aeroplanes used by the British. He says that criticising types is folly, because many different kinds are needed, according to the work on which they are employed, and it is impossible to say which is best.

The writer defends the partial use of second-grade machines as unavoidable, saying that if none but the latest model of each type were used there would be few airmen aloft. He believes that the latest type of the British fiighting plane is equal to the German, but that a greater number of them is needed. This machine is operated by a lone aviator and carries two guns.

In reference to the wear and tear of machines and the strain on the pilots, the correspondent says that the life of an aeroplane does not exceed two months, while the pilots, who are mostly 19 or 20 years old, have to fight for two months before they are much good. The strain is so great that few can stand it for more than three, six, or nine months.

The writer contends that the British have not enough men or enough divisions in the field and says that the severity of the present fighting adds to the gravity of the question.

"Victory or defeat," he concludes, "depends on man power and nothing else stands between us and success."

British Headquarters in France, May 12th, via London.—One of the chief topics of conversation along the whole British front this week has been the disappearance of Captain Albert Ball, the star airman of the British Army. He was last seen near Lens, between half-past six and seven o'clock on May 7. At that time he was engaged with three German machines. He was not seen to fall, however, and no word has been heard thus far from the German aerial corps as to whether he was killed or captured. This is unusual, as the rival air services ordinarily notify each other promptly by messages dropped from aeroplanes of the fate of men who have met with mishaps.

In less than a year Captain Ball had become one of the heroes of the war. Every soldier in the British army knows scores of stories about his prowess and his dexterity in the air. Both he and his friends in the aerial corps had a fatalistic belief that he bore a charmed lfe and could not be killed while flying. Even now the army believes this charm holds and that he is a prisoner, having merely caught an unlucky bullet in some vital part of his machine, forcing him down within the enemy's lines.

Captain Ball had received the Distinguished Service Medal with two bars and also the Military Cross. He lived in Nottingham. When he first entered the army he was wth the Sherwood Foresters. His active service has been with the flying corps, which he joined when he was nineteen years old. He celebrated his twentieth birthday a little while ago.

The missing aviator was of the type of mere boys who make up the flying corps, entire squadrons frequently averaging only twenty-one years of age. He was taken back to England last autumn for a rest after having made a most brilliant record in the Somme fighting, when the British first gained mastery of the air. He came back to France only about a fortnight ago and began a new year of work with even more notable performances than before.

London, May 7.—"In the early hours this morning," says an official announcement to-day, "a hostile aeroplane appeared over the outskirts of Northern London and dropped four bombs. One man was killed and a man and a woman injured. Slight damage was done to buildings."

No one in the area attacked saw anything of the machine. People were awakened by the explosions, but when they reached the street the machine had disappeared. The bomb which caused the casualties fell on the roof of some residences and the other missiles landed in a swamp.

London, May 13.—A considerable raid was carried out on Zeebrugge, the principal German naval base on the Belgian coast, by the British navy and air service early yesterday morning, and although German reports deny that any considerable damage was done, reports from Holland are that two submarine sheds were blown up and nine German aeroplanes shot down.

"A very heavy bombardment of the important area at Zeebrugge was successfully carried out Saturday morning by a portion of our forces under orders of the Dover Vice Admiral," says the British official bulletin.

"The Royal Naval Air Service rendered valuable co-operation, and over fifteen aerial combats occurred, in which four enemy machines were destroyed and five others driven down out of control. Two of our machines failed to return. One of these descended in Dutch territory and was interned."

The German official version of the report is that "enemy monitors, during foggy weather, early Saturday morning, shelled Zeebrugge from a great distance. Our batteries replied. There was no loss of life. Slight material damage was done. Two enemy aeroplanes were shot down."

Despatches from Rotterdam say the raid was the most destructive yet made on Zeebrugge, which has been many times attacked by air and sea in the past two years. Sixty-three were killed and upward of 100 wounded in the destroyed boat sheds.

ITALY

The official report of May 12th, telling of operations the day previous, follows:

"There was lively aerial fighting on both sides. Enemy aircraft last night dropped bombs on Punta Dobba and on some places on the lower Isonzo, causing one casualty. One of our squadrons bombed the railway works at St. Zaniele, in the Branizza Valley, in the Frigidio.

"One of our Caproni machines reached Pola and with bombs caused a fire in the arsenal.

"Enemy aeroplanes repeatedly attempted yesterday to make raids on our territory. They were everywhere driven off by our anti-aircraft guns and airmen. Only one hostile machine succeeded in reaching Brescia and it did not drop any bombs."

JAPAN

The following is from the *Japan Times* of March 24:

The editorial department of the National Aviation Society of Japan has sent a unique tribute to Art Smith, the famous boy aviator, who recently made a series of flights in Japan and is returning to Japan on the Siberia Maru, due in a few days, says a recent issue of a San Francisco paper. The book is entitled "The Aeroplane as a Factor in Bringing Japan and the United States in Closer Friendship," and is made up of press notices telling of his various experiences. He is at the St. Francis Hotel now and has received 200 copies of the book for distribution in this country. Following are excerpts:

"At 8 o'clock, March 18, 1916, Art Smith arrived at Tokyo station. On the platform there stood a general with a long white mustache, who cordially welcomed the famous aviator from America. The general is none other than Lieutenant General Nagaoka. Receiving the warm hand shakes and cordial word from General Nagaoka, Art Smith exclaimed: 'Oh, how could I ever thank you for such kindness.' "

After his first flight in Tokyo, Art Smith has received the following letter together with one yen bill:

"I have seen your flight our house, together with five other members of the family and we were greatly surprised to see you perform such wonderful flights.

"And we thought that to make such flights it may cost you a great amount of money. And when we thought of that we regretted that we saw your flight free from our house. And we are inclosing one yen bill toward your expenses."

The Formation of Model Clubs

(*Continued from page* 24)

RULES FOR CONTESTS

In our issue of March 19th, we dealt upon the manner in which Model Clubs are formed and the proper course to follow in the election of officers. We now come to the matter of contests. As there are many different types of models so must there be rules to correspond to avoid misunderstandings, and until the club has reached the stage where it may decide upon a particular set of rules under which its members should participate perhaps the following set of rules, applicable to contests for Hand Launched Models, can be adopted. In so far as there are different rules for different contests, namely, R. Hand Launched, R. O. G. and R. O. W. and Mechanical Driven the following rules are used only in connection with contests for Hand Launched Models:

1. A contest to be official must have at least five contestants.
2. Each contestant must abide by the rules of the contest and decision of the judges.
3. Each contestant must register his name, age, and address before the event.
4. Each contestant must enter and fly models made by himself only.
5. Trials to start from a given point indicated by the starter of the trials, and distance to be measured in a straight line from the starting point to where the model first touches the ground, regardless of the curves or circles it may have made.
6. Each contestant must have his models marked with his name and number of his models (1, 2, 3, etc.), and each model will be entitled to three official trials. Contestant has the privilege of changing the planes and propellers as he may see fit, but only three frames can be used in any contest. If in the opinion of the board of judges there are too many entries to give each one nine flights in the length of time fixed, the judges have the power to change that part of rule No. 6 to the following:

    "Six flights will be allowed to each contestant, which can all be made with one model or divided up; due notice must be given to each contestant of the change."
7. No trial is considered as official unless the model flies over 100 feet from the starting point. (The qualifying distance can be changed by agreement between the club and the starter provided the entrants are notified.)
8. Should the rubber become detached from the model, or the propeller drop off during the trial, the trial is counted as official, providing the model has covered the qualifying distance. No matter what may happen to the model after it has covered the qualifying distance the flight is official.
9. Contests should cover a period of three hours, unless otherwise agreed.
10. No contestant shall use the model of another contestant, although the former may have made it himself.
11. The officials should be: a starter, measurer, judge and scorer; also three or four guards to keep starting point and course clear. The first three officials shall, as board of judges, decide all questions and disputes.
12. A space 25 feet square (with stakes and ropes) should be measured off for officials and contestants, together with one assistant for each contestant. All others must be kept out by the guards and a space kept clear (at least 25 feet) in front of the starting point, so a contestant will not be impeded in making his trial.
13. Each official should wear a badge, ribbon or arm band designating his office, and must be upheld in his duties.

(*To be continued*)

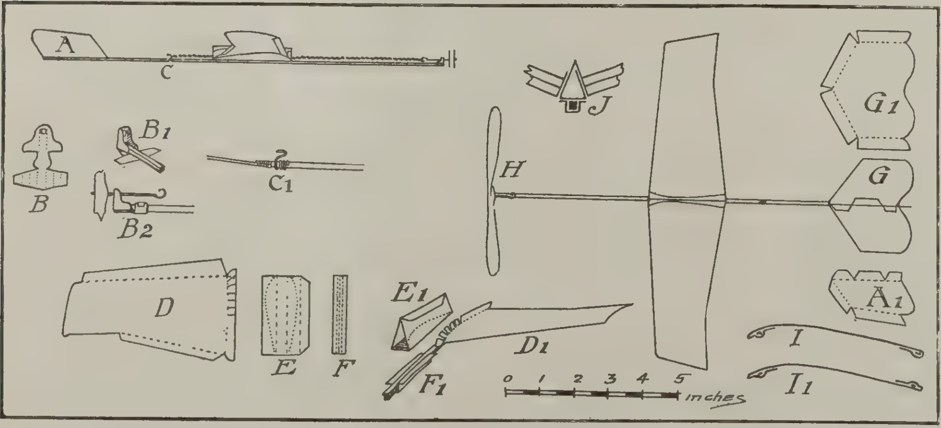
Paper Models

(*Continued from page* 263)

"The wings should be sketched out on paper first, as D, but drawn to full scale. Cut both wings out at the same time, from a double thickness of paper, and fold at the dotted lines. The flaps at leading and trailing edges to be lapped under, and carefully glued down over two very thin cane spars.

"The wing may now be given a curve as in I, which may be produced by rolling the leading half of it round a pencil. Now bend the flaps at the root of the wing upwards, and the result should look similar to D1.

"To construct E, obtain some stouter paper, and cut to shape and dimensions illustrated. Mark out in pencil the wing section, as shown by the fine dotted lines, and fold at the thick dotted lines. This will form a triangular framework, to which the wings may be glued along the pencilled section as D1 to E1. Now cut F from thin paper and glue to backbone as F1, after which the whole may be glued together as J, allowing a free passage for the rubber (which will run above the frame) through the triangular section. The tail construction should, I hope, be self-evident from the diagrams A1 to G1. The flaps in this case are glued down without the insertion of cane spars. The tail, G, is attached to the outrigger in much the same manner as F1, the rudder being glued down by flaps to the top of the same.



"This completes construction, but the beginner should not expect distances in excess of a maximum 150 ft. to be flown by this model. After some experience has been gained, modifications should be carried out, on the lines of the following:

"Lengthen the backbone, so as to allow the use of a greater length of rubber.

"Fit rubber that is normally half an inch longer than the distance between the hooks.

"Glue the rear spar to the top surface of the wing, and lap paper over accordingly, as I 1.

"Endeavor to do without the negative angle of the tail, though at the same time retain the longitudinal stability.

"When trying to obtain a maximum length of flight, lubricate the rubber with soap-jelly (or any other suitable substance).

"The rubber should stand about 500 winds, and should last up from 15 to 20 seconds."

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

A Visit to an Aeroplane Factory

Encouraged by the success of our visit to the Rabid-Radial-Rotary factory a short time ago, we last week decided to pay a visit to the plant of the Hollowspar Aeroplane Company, and see how they were coming along on their machines. Looking up the train schedule, we selected a train—fast freight—and after a trip of eighteen hours, arrived at Wingstrut, L. I., where the famous Hollowspar machines are made. Waiting until the trainman was not looking, we opened the side door, and gently dropped to the ground. Inquiring the way to the Hollowspar factory, and being directed thereto, we decided, for many reasons, to walk to the factory. (The first of our many reasons was that we had no carfare to pay our way, and the rest of the reasons do no count.)

We walked a mile or so, and at last arrived at the factory. Really it was wonderful! We have seen great plants before, among them the gigantic Odor-Engine Plant at Imaginary, New York, but were not prepared for the sight of this magnificent aggregation of buildings which stretched before our astonished view. For miles on all sides the great buildings stretched, while hundreds of workmen stretched (and yawned) all around. One could hear the busy throb of the vast machinery inside, and once in a while could see rays of light issuing from the windows, as one of the workmen got a flash of intelligence.

We stood in front of the buildings for a while, taking notes of the astonishing scenes which confronted our eyes, and then ascended the steps. Arriving at the top of the steps in a little more than a half-hour, we dodged a sledge-hammer which one of the workmen playfully threw at us, and dusting off our clothes, we entered the building.

What a magnificent sight confronted our eyes! We had no idea that an aeroplane factory could afford to employ so many men. We stopped and counted them for a few minutes. In five minutes we counted five thousand men, five thousand women, and about ten thousand other people who were working so fast that we could not tell whether they were men or women. Stopping one of the workmen, by gently tripping him with our foot, we asked to be taken to the president's office.

"The president has no old clothes to sell," he said, and started off.

We called him back, administered a severe lecture to him, and demanded that we be taken to the office of the president. (We later learned the cause for his disrespect. Upon getting into our car, we had unwittingly backed into a freshly painted "Live Stock" sign.) When the workman glanced at our card, we could see a look of extreme awe begin to cover his face.

"I have read some of your stuff," he said.

"Is that a reason for your insulting tone?" we asked.

Without another word he led us directly to the president's office. Pausing at the door, we stopped to read the president's name before going in. Lo and behold! Who was it but Senator J. A. Oszk!

Without saying another word, we dashed through the door and entered just in time to dash off a drink with the Senator. Seating ourselves in front of each other, we started to speak.

"Well, Senator," we said, "it's a long time since we saw each other."

"Marvelous!" he said.

"What is marvelous?" we asked.

"My machine," he responded. "Let me give you a short description of it."

Four hours afterward he stopped to take a breath, and seeing our chance, we interrupted him for sufficient time to write down some notes of what he was telling us. We append a carefully compiled list of the main characteristics of the Senator's new machine.

Name. Hollowspar Speed-Scout.
Stagger. Very pronounced.
High-Speed. 23 M.P.H.
Low Speed. 45,000 R.P.M.
Lubrication. Excellent.
Control. Very easy.
Capacity. Of machine, 354 lbs. Of pilot, 8 seidels an hour.
Motor. Rabid-radial-rotary, or Odor-Engine.
Price. $.65 per square foot. (Cash.)

A Few Lines of Advice

Keep the freight cars moving,
Our industry proving;
Turn the green sod upside down
While the planting's good;
Start the hoe and shovel
From each house and hovel;
Make each patch of ground bring forth
Some kind of food;
Keep the transports sailing
And the U-Boats wailing;
Turn the Germans upside down
In the deep blue sea;
Feed our Allied nations
UNCLE SAM'S war rations;
Turn the tide of battle to HUMANITY.

PERFORMANCE

The New York Aero Construction Company's Twin Motored Seaplane has a maximum speed of 85 miles per hour, excelling the estimate by ten miles per hour. Yet it has a slow landing speed of 43 miles per hour, allowing the landings to be made within a much smaller space than is ordinarily the case. But what is even more important in coast defense work is the fact that it has a

FLYING RADIUS OF NINE HOURS

The advantages of a high speed and a wide flying range are obvious. The coasts of the United States are long, and the swifter the machines that guard them, and the longer they can stay in the air, so much better and more easily are the coasts patrolled. The seaplane mentioned in the editorial of the World could, flying at full speed for its seven hours' flying radius, cover 515 miles. The seaplane of the New York Aero Construction Company could cover 680 miles.

820 Sq. Ft. Supporting Surface. Maximum speed, 85 Miles per hour.
Two 100 H.P. Aeromarine Motors. Minimum speed, 43 Miles per hour.
Weight 2,700 lbs. Useful load 1,700 lbs. Flying radius, nine hours.

Designed and constructed throughout under the supervision of Mr. Warren S. Eaton.

NEW YORK AERO CONSTRUCTION COMPANY, Factory, Newark, New Jersey

(*Continued from page* 323)

J. E. Hale, Goodyear Tire & Rubber Co., inquired regarding the tire sizes which he said are all new. On the other hand, the 26 by 4 has been popular with production running into the thousands and yet these are not mentioned in the report. Duesenberg stated that in the committee meeting no one had made any objections to the tire sizes, although no tire men were present. Hale stated that none of these tires are made but this is a matter which should be considered, and although the situation is by no means grave owing to the relatively small production, it would be a question of making matters much more simpler if existing sizes could be used. Duesenberg pointed out that the 32 by 4½ tire is easily secured and is the normal size for the popular 33 by 5 oversize tire used extensively in racing.

In view of this discussion, Chairman Utz stated that he was willing to receive a motion to the effect that the report be amended so as to exclude the paragraph on tires and rims. This amendment was passed with a suggestion from one of the members that the thickness of the rimstock also be inquired into, because of the difference between that recommended and that now used.

Another matter in connection with the report of the aeronautic division was brought up with regard to the specifications on sheet metals. These were stated to be not full enough, particularly as regards steels, which had to be bent on themselves before heat-treated. Metallurgist Zimmerschied of the General Motors Co. was one of those who concurred in this, and the result was the addition of another amendment excluding that part of the report dealing with the iron and steel specifications, both amendments being carried without any dissent.

Standardizing Tachometer Drive

C. M. Carson, consulting engineer of the H. W. Johns-Manville Co., drew attention to the matter of standardizing tachometer drive, which is under consideration. He stated that where flexible cables of a length up to 16 ft. long are used, the bends in the cable are apt to change the length of the shaft to such an extent that it is doubtful if the keyway suggested is sufficient to hold the engaging members of the driveshaft in place. Berne Nadall of the Stewart-Warner Speedometer Co. concurred in this and others pointed out that the wall is rather thin in the suggested speedometer drive end, whereas in aeronautic work it is necessary to have a rigid fixture at this point. This discussion resulted in the three amendments to the report, which was finally accepted with these three amendments; namely, that the maters of tires, iron and steel specifications, and tachometer drive should be turned back to the division for further review.

(*Continued from page* 328)

valve which showed slight pitting in the seat was the only part replaced. No other valves were reground, no bearings readjusted, and no other parts altered or adjusted in the slightest degree. The bearings, both main and connecting rod, were accurately measured and no wear could be detected. The wrist pins, cylinders and pistons were also carefully measured and no wear could be detected.

"The engine was then reassembled and run for one hour during which the following readings were taken:

Time H.M.	Motor R.P.M.	H.P.	Oil Pressure	Water Inlet	Water Outlet
0	1811	308	68	94	134
15	1835	312	69	99	132
30	1848	314	60	103	135
45	1801	313	57	98	134
1:00	1835	317	58	102	134
Average	1826	312.8	60.4	99.2	134

"These readings are plotted in Fig. 3.

"During the hour of this run the temperature varied from 61 to 74 and the barometer reading was 29.65 Hg. During this run 32 gallons or 199 pounds of fuel was used, making the consumption of fuel equal to .5715 pounds per horsepower hour.

"The oil consumption was .0435 pounds per horsepower hour.

"The brake m.e.p. was 91 pounds per square inch and the thermal efficiency 23.55 per cent.

"The water pump output was determined before the official test and is shown in Fig. 4."

(*Continued from page* 327)

gain are claimed. This seems hardly possible except that practically every successful six cylinder aeroplane engine on the market makes use of two carburetors. Another feature is the use of a double ignition system; two independent magnetos and two sets of independent spark plugs to each cylinder. The deep oil sump with the oil pump at its lowest point is another characteristic. Practically no aeroplane engine is lubricated by splash, high pressure lubrication being used exclusively. One of the chief points in which designers of this type of engine have a chance to show their ingenuity is in the combination of the cam-shaft drive with the drive for the magnetos and pumps. In this engine a bevel gear on the crank-shaft meshes with the bevel gears at the extremities of two vertical shafts, the upper driving the megnotos and cam-shaft thru bevels, and the lower driving the centrifugal water pump seen at the lower extremity to the right, and in addition a horizontal shaft which in turn drives two oil pumps in the lowest part of the crank-case. It is a very neat arrangement.

From the remarkable performance of these engines before the war, it is natural that we should be very inquisitive about the developments which have taken place under the stress of war service. From the latest reports it seems that but few changes have been made. The cylinders are increased in diameter from 4¾ to 5½ inches, so that the engine develops a maximum of 165 horsepower instead of 100. The cylinders are now individual instead of in pairs, but retain their welded steel water jackets. The drive of the cam-shaft and auxiliaries has been modified, so that the water pump is just below the cam-shaft bevels, the rotor being mounted on the vertical driveshaft which passes through it. This gives room for the oil pump where the water pump was formerly, and simplifies the drive of the former. All these changes are merely design refinements which considerably reduce the cost of manufacture and make the parts more accessible. The only departures from former designs in principle are the addition of cooling ribs on the bottom of the oil sump, and a set of decompression cams which are thrown into action by sliding the cam-shaft horizontally, and makes starting the engine by hand a fairly easy task. This is a matter of no small importance in an engine of this size.

ALWAYS KEEP THE CHART IN SIGHT

Aeronautic Maps

THE Aeronautic Library has secured the exclusive agency from the Sperry Gyroscope Company for the sale of the Sperry Aeronautic Maps and is now ready to deliver maps New York-Chicago; New York-Newport News; Long Island and vicinity, etc.

Every aviator appreciates the value of an accurate map when making cross-country flights, and the Sperry Aeronautic Maps, and Sperry Map Holder, supply this necessity.

The map can be turned easily in the holder bringing constantly before the aviator a chart of the locality above which he is flying.

The equipment is light in weight and can be fixed to instrument board without interference with the other instruments.

Prices and details on application.

(*Continued from page* 321)

(c) *Instructors.*—Instructors must be men of experience in flying and thoroughly competent to teach through the reserve military aviator stage. They should be level headed, have good judgment, and sufficient mental balance to impart what they know.

(d) *Character of instruction.*—The course of instruction will be divided into two stages. The first stage will include instruction and qualification through and to include the preliminary flying test. This test will be held under the supervision of an officer or agent of the aviation section of the Signal Corps. The second stage, which is optional with the school authorities, will consist of advanced training necessary to qualify an aviation student as a reserve military aviator. An advanced training type of machine will be used at least during the last stages of this instruction. Detailed information as to the course to be followed in this stage will be furnished the school authorities. The reserve military aviator test will be held under the supervision of an officer or agent of the aviation section of the Signal Corps.

(e) *Preliminary flying test.*—(1) Three sets of figure eights around pylons 1,600 feet apart. In making turns around pylons all parts of machines will be kept within a circle whose radius is 800 feet.

(2) Stop motor at a minimum height of 300 feet and land, causing machine to come to rest within 150 feet of a previously designated point.

(3) An altitude test consisting of rising to a minimum height of 1,000 feet.

(4) Glides with motor throttled, changing direction 90° to right and left.

NOTE.—(1) and (2) may be executed in one flight; (3) and (4) in one flight. The same rules apply in starting from and landing on water. Special attention will be paid to the character of landings made.

Should any aviation student desire to take the pilot license test prescribed by the International Aeronautic Federation, facilities will be afforded him.

Report of these tests will be submitted to the officer in charge of the aviation section, with the information as to whether or not the school will complete the training of the aviator through the reserve military aviator stage.

If the preliminary flying test is passed satisfactorily and a candidate qualifies in other respects, he will be eligible for further instruction to qualify as a reserve military aviator.

(f) *Reserve military aviator test.*—Reserve military test will be as follows:

(1) Climb out of a field 2,000 feet square and attain 500 feet altitude, keeping all parts of machine inside of square during climb.

(2) Glides at normal angle, with motor throttled. Spirals to right and left. Change of direction in gliding.

(3) At 1,000 feet cut off motor and land within 200 feet of a previously designated point.

(4) Land over an assumed obstacle 10 feet high and come to rest within 1,500 feet from same.

(5) Cross-country triangular flight of 30 miles, passing over two previously designated points. Minimum altitude 2,500 feet.

(6) Straight-away cross-country flight of 30 miles. Landing to be made at designated destination. Both outward and return flight at minimum altitude of 2,500 feet.

(7) Fly for 45 minutes at an altitude of 4,000 feet.

If, in addition to the preliminary flying test the candidate also passes the reserve military aviator's test satisfactorily, he will be given a commission in the aviation section, Signal Officers' Reserve Corps, provided all other qualifications are fulfilled.

All candidates for the aviation section, Signal Officers' Reserve Corps, will be required to pass the prescribed physical examination, must weigh not more than 190 pounds, stripped, must furnish evidence of having a college education or its equivalent, and be of good moral character.

Applicants for commissions as reserve officers, who hold the pilot certificate of the International Aeronautic Federation may, after successfully undergoing the prescribed examinations, be given a flying examination embodying at least the requirements of the preliminary flying test. If competent they may also take the reserve military aviator's test.

25. BALLOON SCHOOLS—SPECIAL REQUIREMENTS.

(a) *Pay for tuition.*—Each balloon school will receive compensation for instruction of such personnel as may be assigned thereto, and reimbursement for average breakage to be determined in a manner similar to those at civilian aviation schools.

(b) *Character of instruction.*—The course of training will include qualification of pilots of free balloons according to the standard fixed by the International Aeronautic Federation, supplemented by practical work with captive balloons. Before qualification, balloon students must have made at least 10 ascents in captive balloons, 5 of which have been at an altitude of at least 4,000 feet. Upon completion of this course, qualified students may receive advanced instruction in the rapid maneuvering of military captive balloons by organized balloon companies at the United States Army balloon schools or during field service. They will then be eligible for commission as reserve officers and assignment to tactical units.

An application for a commission in the aviation section, Signal Officers' Reserve Corps, who holds the balloon or dirigible balloon pilot certificate of the International Aeronautic Federation may, after successfully undergoing the prescribed examinations, be given a test to demonstrate his qualifications. Provided these and all other qualifications are fulfilled he will be eligible for a commission in the aviation section, Signal Officers' Reserve Corps. As soon thereafter as practicable and with his consent he may be assigned to active duty at any Army balloon school or with a balloon company on field service for advanced training in the application of ballooning to the special requirements of the military service.

Experienced balloon pilots and candidates for commissions in the aviation section, Signal Officers' Reserve Corps, who desire training in military ballooning should submit their applications in the same manner as other candidates for reserve commissions, expressing in the letter preference for the aerostatic service. The physical, moral, and educational requirements for reserve officers of the balloon service are the same as for aviation duty. The course of technical balloon training will require about four months.

SECTION VI.

DETAIL OF OFFICERS AND ENLISTED MEN OF NATIONAL GUARD AT SIGNAL CORPS AERONAUTICAL SCHOOLS.

Par.
Applications and examinations.............. 26

26. APPLICATIONS AND EXAMINATIONS.—Officers and enlisted men of the National Guard not in the Federal Service may be detailed at Signal Corps aviation or balloon schools under section 99 of the national defense act. National Guard officers and men desiring such course will apply to the adjutant general of their State, who will forward the applications direct to the Chief, Militia Bureau, War Department, Washington, D. C. Such officers and enlisted men will be required to pass the prescribed physical and mental examinations, which will be similar to those required of reserve officers, aviation section, Signal Officers' Reserve Corps. On approval by the Militia Bureau orders will be requested from The Adjutant General of the Army assigning such officers or enlisted men to duty at aeronautical schools. Officers and enlisted men of the National Guard in the Federal Service desiring a course of aeronautical training will make application through their commanding officer to the Adjutant General of the Army, stating their qualifications for the work. Blank form of application will be furnished upon request to the Adjutant General of the Army.

Burgess Primary Training Tractor Type B. P.

This machine was designed by W. Starling Burgess at the request of the United States Army for a primary training tractor aeroplane having a practical side by side seating arrangement with duplicating controls.

This has been accomplished without sacrificing in the least the efficiency or appearance of the machine.

It fills the urgent need found at present in the aviation schools—giving great range of control and allowing the instructor to be at side of the pupil during flight, thereby facilitating instruction.

This has proven very satisfactory in experimental flights as well as in the official trials thru which this machine passed with great success.

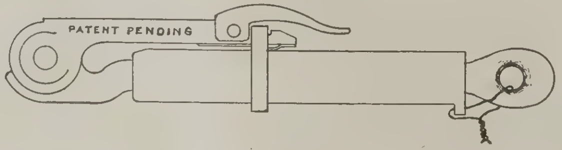
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

Quotations and deliveries on request.

Aeroplane Spruce

Close, Straight Grain, 4 Sides Clear

Guaranteed to be the Finest and Strongest aeroplane timber offered

PRICES ON APPLICATION

All price quotations withdrawn. There has been a rise of ten to twenty-five dollars per thousand feet on all classes of this lumber during the last thirty days, and the probabilities are that the grade 3 inches thick and thicker, 6 inches wide and wider, ten per cent; 10 to 17 feet long, ninety per cent; 18 to 40 feet, seventy-five per cent vertical grain, **four sides clear** straight grain, not less than ten annular rings to the inch, will be $200.00 per thousand f. o. b. New York within sixty days. Many foreign buyers are on the Pacific Coast and are taking all offerings. It is advisable to place contracts at once for a season's supply before the price rises further or the grade is exhausted. No aeroplane spruce older than 4 to 6 months is available and spruce should be air dried nine months and longer to achieve the best results. In purchasing, care should be taken to buy from a specialist the grade known as **four sides clear, free from all knots and sap pockets.** Some aeroplane builders not conversant with these specifications have made purchases which were practically valueless for construction work.

The Buck Automatic Aerial Torpedo

AFTER a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

Air Production Board Formed to Develop Aeronautics

Two Billion Dollar Liberty Loan Aerial Rally Proposed

INSURANCE AGAINST ACCIDENT

ABOUT 90% of the accidents on the training field are attributable to mistakes in landing—usually resulting in the collapsing of wheels and their supports.

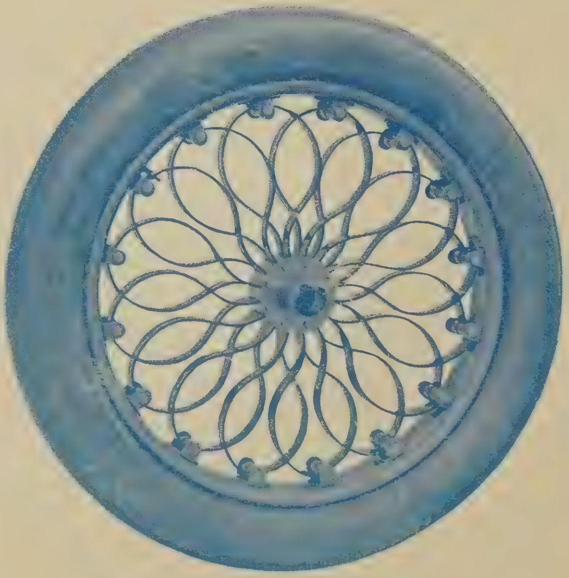
Exhaustive tests in actual service have demonstrated that Ackerman Aeroplane Wheels eliminate this source of trouble, and as soon as the inherent prejudice concerning "something new" has been eliminated, every machine that is produced in this country will be equipped with Ackerman Wheels.

Beyond the greater factor of safety which the Ackerman Wheels insure, they have many other points of advantage over the ordinary types of aeroplane wheels.

First: They are lighter in weight.

Second: They are constructed in such a way that they can be streamlined more efficiently.

Third: Their wonderful strength and resiliency are best evidenced by their ability to absorb shock and prevent rebound in landing and getting away.



Ackerman Wheels are built in different sizes to carry any load from 500 pounds and up

AIR PRODUCTION BOARD FORMED TO DEVELOP AERONAUTICS

Orders Being Placed for 3,500 Aeroplanes and Steps Taken to Begin Training 5,000 Aviators

AN Air Production Board has been established at last to take up in an energetic way the work of developing our aerial defenses. We give herewith the first announcement of the preliminary plans, which are at present handicapped by lack of sufficient appropriations.

The limitations imposed by insufficient appropriations are serious, but the Aero Club of America and its constituent organizations are pledged to carry out an extensive campaign of public education, if necessary, to make Congress realize the necessity of allowing the appropriations to enable us to make a substantial start, and which will permit looking forward to the production of the 20,000 aeroplanes needed to train and equip the 5,000 aviators in the shortest time possible.

It has been estimated that it takes an average of half an aeroplane for each aviator trained, and that even with the utmost care 25 percent of the student aviators do not become military aviators, and have to be divested to other branches of the air service, where they do not have to pilot an aeroplane, although their services are of equal importance. Therefore, there will be required, roughly speaking, 5,000 aeroplanes to produce 5,000 military aviators, allowing the difference between one-half an aeroplane to each student and the 5,000 mentioned for those that will not qualify as aviators and the training of observers.

As a military aviator must now be able to pilot an aeroplane going at a speed of close to 120 miles per hour, there will be an intensive training required with fast machines, which will undoubtedly increase largely the number of machines needed for the training of the 5,000 military aviators.

After the aviators are trained there will be required three aeroplanes to equip each aviator, making 15,000 additional aeroplanes needed for equipping the aviators and making a total of 20,000 aeroplanes needed within two years.

The personnel of the newly appointed Air Production Board is as follows:

Howard E. Coffin, chairman; Brig-Gen. George O. Squier, signal officer, U. S. A.; Chief Constructor Taylor of the navy, S. D. Waldon, Major in the Officers' Reserve Corps; E. E. Deeds, former general manager of the National Cash Register Company, and R. L. Montgomery of the Philadelphia firm of Montgomery, Clothier & Taylor, who will serve as financial and business adviser.

Mr. Coffin is a Governor of the Aero Club of America, and as will be remembered was chairman of the Organizing Committee of the First Pan American Aeronautic Exposition. General Squier and Messrs. Waldon and Deeds are also members of the Aero Club of America. Mr. Waldon is a Major in the U. S. Army Aerial Reserve Corps, and Mr. Deeds gave a demonstration of his practical patriotism recently by offering to establish training camps for aviators.

The preliminary announcement of the Air Production Board is as follows:

"We now believe America has started on the right road toward working out her destiny in the air and taking the place to which her capacity entitles her and which the world expects of her. We have been in constant touch for weeks with the aircraft manufacturers on the problem of the quantity production of machines, and the Government authorities are already signing contracts for as many machines as our present appropriation permits. The United States can depend on a minimum of 3,500 aircraft of all types the first year, if Congress authorizes us to proceed. The program we now have in mind would provide for both training and combat machines.

"Only a few American manufacturers are in a position to handle large contracts, but European orders for training machines within the last two years have helped in some measure to overcome a tremendous disadvantage existing at the beginning of the war.

"In building battle planes the engine is the chief problem. American manufacturers are now conducting successful experiments with both new and foreign types; and we are confident that we shall be able to develop within the year the manufacture of motors of sufficient power and endurance for use at the front. It is a matter of common knowledge that up to this time, with few exceptions, the only machines which America has turned out for use abroad have been training types.

"Whether we turn out large numbers of machines fast and powerful enough for use at the front or not, however, all that we manufacture will be of value to the Allies, since the more training machines we turn out here the more factories in England and France are released for the manufacture of fighting machines. It is highly probable, indeed, that our shipments abroad may consist at first largely af aircraft engines, since they are compact, and shipping whole planes might easily require more shipping space than the Allies would wish to give up to that purpose.

"Arrangements have been made with British and Canadian officers to standardize the training machines in use in Great Britain, Canada, and the United States, so that machines can be distributed impartially and without difficulty among the three nations. We hope to be able to make satisfactory arrangements with the British and French manufacturers to secure the advantage of their experience and designs in spurring forward the development of our own industry. All reports that the United States intends to purchase aeroplanes abroad are manifestly false, since the Allies are constantly in need of more machines than their own resources can supply.

"The country has made progress in developing aviators. Last month a group of army officers visited the training camp of the Royal Flying Corps at Borden, Ontario, one of the four camps established in Canada and the aviation school at Toronto, where cadets are trained under military discipline for the service. In these schools there has been incorporated the latest European experience in the development of this new art of the air.

"Our officers were deeply impressed with their observations, and as a result we called together here the heads of six prominent engineering schools which also have military training, and made plans to establish a similar system in the United States. The six institutions are the Universities of California, Texas, Illinois, Ohio, Massachusetts Institute of Technology, and Cornell University. Three technical instructors from each of these places were sent to Toronto. They returned on May 8 after a comprehensive study of the course given there, prepared to teach it themselves. On May 10 these six engineering schools opened similar cadet aviation schools at their respective institutions. At the end of two months of this preliminary work, the cadet is given a final test to determine whether he shall go on to the aviation camp.

"General Squier's office has been handling these schools, over which Professor Hiram Bingham of Yale has been given general direction, and there have been far more applicants than could be admitted. Twenty-five cadets a week are entering each of the six colleges, which means that as soon as the first entering class completes its preliminary work approximately 150 students a week will be available for the regular training camp. There will be 600 cadets in the six colleges by July 1.

"In the meantime plans are going ahead for the nine aviation fields to receive the men when they are ready. The standard field on which we are basing our program will provide for accommodating two squadrons of 150 students each, with the necessary officer instructors and enlisted men, together with a certain number of additional enlisted men who will be training at the same time. The hangars will take care of 72 planes. The preparation of these fields will cost approximately $1,000,000 each, including the construction of the necessary buildings, dormitories, workshops, and hangars. The fields will be approximately a mile square.

"We are estimating about four months as the period for getting those students ready for army service. The Aircraft Production Board is working hard to assist the military departments in their plans to have all these related activities co-ordinated. These new plans will not interfere in any way with the present use of the four aviation fields the Government now has, nor with private initiative. It is doubtful if the Government can make any particular use at present of private fields, because they are not training their men under military discipline.

"The manufacturing capacity can easily be doubled the second year. A prominent British General has asserted that America's greatest contribution to the war will be aircraft and aviators. We believe that, once started upon quantity production, American mechanical genius will overcome any present obstacles to the progress of the art."

1,800 AEROPLANES NOT TO BE ORDERED FROM FRANCE

On May 15th a Washington despatch was printed in the press throughout the United States that orders had been placed in France for 1,800 aeroplanes for the United States Army. This report was received with a general feeling of misapprehension by the public and press of the United States, and the Aero Club of America immediately entered a vigorous protest. The protest stated that this project would place additional burdens on our Allies instead of helping them, and would further delay the work of establishing sources of supplies for military aeroplanes in this country.

The protest, which is signed by Mr. Alan R. Hawley, President of the Aero Club of America, is addressed to Secretary of War Baker, Secretary of the Navy Daniels, the Council of National Defense, the National Advisory Committee on Aeronautics, the Chairman of the Committee on Military and Naval Affairs in both Houses of Congress.

The protest quotes Mr. André Tardieu, the newly appointed High Commissioner for France in the United States, and Mr. Pemberton-Billing, a member of the British Parliament, who have been urging that the United States assist the Allies by supplying to the Allies between 5,000 and 10,000 aeroplanes as soon as possible.

It is also pointed out that insofar as equipping American aviators with fast fighting planes is concerned, we must give these men the six months' training necessary to train them to the point where they can handle machines capable of going at a speed of 115 miles an hour, which is the speed of the present American aeroplanes.

The letter sent to Secretary Baker and the other officials mentioned reads as follows:

"Dear Mr. Baker—

"(1) We beg to submit that the plan to place orders in France for 1,800 aeroplanes for United States aviators places an additional burden on our Allies instead of helping them and will greatly delay the establishing of sources of supply for military aeroplanes in this country.

"(2) We have given close consideration to the subject and find that our Allies agree in the advisability of immediately developing manufacturing facilities in the United States to supply them with a large number of aeroplanes thereafter. M. André Tardieu, the newly appointed High Commissioner for France in the United States, who is a member of the French Chamber of Deputies, and knows the extent of the manufacturing resources of the United States, in his statement to the press dated, April 28, said:

"'As regards war material, there is one thing in which the United States could collaborate at once—the manufacture of aeroplanes. French specialists should be sent over to give American workers the finishing touches in certain processes in which the latter are wanting. The motors, as an instance, hitherto delivered by the United States, have not the same finish as those made in France. All American factories able to take part in such production should be set to work at once. An inventory of those able to make aeroplanes must be made. It may be said that we have not enough technical workers to spare, but if a short slackening in our output can assure us in four months five or six times greater results, should we hesitate? It is a question of figures, calculations and estimates.'

"In the British House of Commons on April 26th, Mr. Pemberton Billings, a member of Parliament, in an address urging the British Government to co-operate with the United States in developing sources of supply for aeroplanes in the United States, said:

"'It would be quite possible for the American nation without any great strain on their resources either of personnel or of material, to raise 5,000 or 10,000 bomb-dropping machines in the next six or eight months. I think it also feasible that they might be able to provide at least half that number, which would be a very fair average to allow for crashes; and, I think, if this war does continue through this year, as it seems likely to continue, it would be a very useful thing for the Allies if the Americans could put from 3,000 to 5,000 bomb-dropping machines on the Western or on the Eastern front early next year. The effect of raids carried out on a vast scale, as they could be carried out, without any trouble to ourselves or any drain on our resources beyond supplying America with the drawings and specifications and possibly one or two machines to help them through the initial stages, would be incalculable.'

"(3) We beg to suggest that whereas the U. S. Army has just adopted the British and Canadian system of training aviators, which involves putting every student through a course of training requiring from six to nine months, as stated by the National Advisory Committee on Aeronautics, we can turn out fighting machines in large numbers long before we have the aviators to fly them.

"(4) As a matter of fact, an aviator trained to fly the present fast American aeroplanes, which have a speed of up to 115 miles an hour (and a high factor of safety of six) will have no trouble whatever in piloting the lighter European machines, which have a speed of 120 miles per hour, but have only a factor of safety of two. When fighting the enemy aviators this additional five miles an hour is of vital importance, but for training to the fighting point the American machines are best, as they bring the same results, without involving the aviators into risking their lives in training with the lightly built European machines.

"Assuring you of the hearty co-operation of the Aero Club of America and its thirty constituent aero clubs in every way in which we can assist in the upbuilding of our national defenses, I remain,

"Yours very sincerely,
(Signed) Alan R. Hawley, *President,*
"Aero Club of America."

TWO BILLION DOLLAR LIBERTY LOAN AERIAL RALLY PROPOSED—AERO CLUB OF AMERICA OFFERS $10,000 IN LIBERTY BONDS AS PRIZES

The assistance of the Aero Club of America and its thirty constituent clubs has been requested by the Liberty Loan Committee for a campaign of education on behalf of the United States Government two billion dollar war loan and, as part of this campaign, it is proposed to have a race across the continent over the Lincoln Airway, which extends from New York to San Francisco. The Aero Club of America has already done energetic work on behalf of the Liberty Loan and has invested close to forty thousand of the club's funds and prize funds in Liberty Loan bonds. Many of its wealthy members have also subscribed extensively in Liberty Loan bonds.

The plans for employing aeroplanes in the campaign of public education on behalf of the Liberty Loan were discussed by the officers of the club and representatives of the Liberty Loan Committee two days ago, and this morning Mr. Alan R. Hawley, president of the Aero Club of America, received the following letter from Mr. Burnett Townsley of the Committee on Publicity Education of the Liberty Loan Committee, of which Mr. Frank A. Vanderlip is chairman:

"Alan R. Hawley, Esq.,
"President, Aero Club of America,
297 Madison Avenue, New York City.

"Dear Mr. Hawley:

"Confirming our conversation, the Liberty Loan Committee invites the cooperation of the Aero Club of America and its constituent clubs, in a campaign of public education on behalf of the United States Government $2,000,000,000 war loan.

"Our Committee is particularly interested in the plan suggested by Messrs. Henry Woodhouse and Augustus Post to run a race across the continent over the Lincoln Airway. We are also interested in the plan to make an aerial circuit of the country, as it were, by sending aviators from each of the military and civilian aeronautic stations to other points, so as to practically touch simultaneously the important geographical points by aeroplanes carrying educational pamphlets and circulars relative to this patriotic enterprise during the week of June fourth.

"As this campaign of public education is undertaken by direction of the United States Treasury Department, we believe that it will be possible to secure effective cooperation of the Army and Navy Aviation Sections.

"Therefore, may we urge you and your Board of Directors to appoint at your earliest opportunity a committee to consider the advisability of conducting such a race and to suggest other ways and means by which your excellent Club and its constituent clubs may cooperate with our Committee in this patriotic service.

"Your suggestions and advice will be heartily appreciated.

"Very truly yours,
"LIBERTY LOAN COMMITTEE,
"By Burnett Townsley."

The Executive Committee of the club is communicating with its thirty constituent aero clubs and appointing the committee to carry out a nation-wide aerial campaign for public education on behalf of the two billion dollar war loan.

If possible, the Liberty Loan Aerial Rally will be conducted during the week of June 4th, the day selected by the Liberty Loan Committee, which will make it possible to

(*Continued on page* 365)

THE NEWS OF THE WEEK

The D N-1 in Use at Pensacola

Washington.—The first dirigible balloon to be used by American military forces is in operation at the Pensacola Naval Aeronautic Station. It is known as D N-1, and is being used to train crews to handle the fleet of sixteen coast defense dirigibles soon to be delivered by the builders.

Thousands of men from all parts of the country have applied for enrollment in the Naval Reserve Flying Corps. Since only a limited number of men was desired, the Department has been able to select with great care the men it desires.

S. A. E. Summer Meeting at Washington

Definite plans concerning the summer meeting of the Society of Automotive Engineers, to be held June 25 and 26 at the Bureau of Standards. Washington, were settled at the May meeting of the Council of the Society, which was held in the new S. A. E. offices in the Munsey Building.

An informal dinner will be held in the banquet hall of the New Willard Hotel, Tuesday evening, June 26. Secretary of War Newton Baker has accepted an invitation to be present and address the engineers. The other speakers have not been dcided upon as yet. The dinner will be $6.00 per plate, and members are asked to make reservations through the New York office of the S. A. E. It is expected that this dinner will be the greatest get-together of the Government officials and S. A. E. members in the history of the Society. Over thirty guests representing the Army and Navy from Washington will be present.

The professional session on Tuesday, June 26, will be one of particular interest. The majority of the papers to be presented have already been decided upon, and they all will be of a practical type. Wing Commander I. W. Seddon, R. N. A. S., who is a member of the British Commission in this country, and who is demonstrating some of the British types of war aeroplanes here, has agreed to present a paper dealing with the practical aspects of airplane manufacture, and to include much other information greatly needed by manufacturers and engineers. Commander Seddon has had much practical experience on the Somme Front.

Major Rees, also of the British Commission, an experienced British aviator throughout the entire Somme Campaign, who accompanied the Commission to give practical information on what aeroplanes of different types are actually called upon to do, has practically agreed to answer various questions on this interesting subject.

Anti-Aircraft Gun Battery Has First Drill

Fifty members of the Brooklyn Battery of the First Anti-Aircraft Regiment were drilled in the armory of the Twenty-third Regiment, Bedford and Atlantic Avenues. It was the first drill of the organization, which has five batteries in Manhattan and Brooklyn. The men are working on the lines of a similar organization in London. Guns have been ordered, and it is expected that the men soon will be instructed in their use.

Large Training Camp at Wilmington

A large aviation training camp for training men for the Army and Navy Aerial Reserves is being established by Messrs. Pierre DuPont, Irenee DuPont and J. J. Roskob, of Wilmington, Del., and the Aero Club of America's co-operation and advice has been requested, and the Club is asked to refer students to be trained free of charge.

Authoritative details regarding this plan are made public for the first time in the letter addressed to the Board of Governors of the Aero Club of America by Mr. Harry N. Atwood, the veteran aviator and aeronautic engineer, who has been appointed in charge of this school. The letter follows:

"The Board of Governors, Aero Club of America,
New York City.

"Gentlemen: To help the Government in getting aviators for the Army and Navy Aerial Reserves, Messrs. Pierre DuPont, Irenee DuPont and John J. Roskob decided recently to establish an aviation camp and train men suitable for the air service free of charge.

"Steps were promptly taken to carry this plan into effect and establish a land and water aviation training school. The site for the aviation field, which is located at Claymont, at the edge of the Delaware River, is part of Mr. J. J. Roskob's estate. It is splendidly located, affording facilities for both land and water flying.

"The preliminary equipment is to consist of six aeroplanes and seaplanes, with the necessary spare parts and spare motors. This equipment has been ordered, and delivery of four of the machines is to be made within a few days.

"The aviation school is to open on June 1st, and the plan is to put under training as soon as possible fifty students.

"As the purpose of Messrs. DuPont and Roskob in establishing this aviation training school is to assist the Government by giving preliminary aviation training to suitable men, the candidates for the training will be required to pass the physical examination prescribed by the Army and Navy for aviators, and will be men having a college education or its equivalent.

"The co-operation of the Aero Club of America in carrying out this plan will be greatly appreciated. As the Club has done so much in the past towards getting and training aviators for the Reserves, you are in a position to make valuable suggestions resulting from your experience, and to refer to us suitable men who have applied to the Club for aviation training.

"Kindly refer applicants to the writer, who is in charge of this project. My address is Hotel DuPont, Wilmington, Del.

"Assuring you that your co-operation and advice will be greatly appreciated, I remain,

"Very sincerely yours,
(Signed) "HARRY N. ATWOOD,
General Manager."

It will be remembered that Harry N. Atwood was one of the first few original American aviators. In 1911 he made the then extraordinary flights from St. Louis to New York, and Boston to Washington. In the St. Louis flight he covered a distance of 1,265 miles, and in the Boston to Washington flight, he covered 818 miles. On his arrival at Washington he landed on the White House grounds, being the first aviator to land on the White House grounds.

Standard Aero Corporation Offers Machines to Civilian Organizations

The management of the Standard Aero Corporation has asked AERIAL AGE to announce that in order to encourage and increase aviation training, Government officials have authorized the sale to private parties of Standard Model "J" Training Machines, built for the Government to full specifications, and passed by Government inspectors. The "J" has a high factor of safety, and is equipped with a special safety landing gear, as shown, which prevents nosing over. It has a low landing speed of 37 m.p.h. Several of these machines that have passed Government inspection are now complete and ready for immediate delivery from the Standard Aero factory at Plainfield, New Jersey. A large number of these are being built for the Government use, thus assuring quick deliveries of spare parts.

Admiral Peary in Chicago

Rear Admiral Robert E. Peary spoke at a dinner given by the Aero Club of Illinois on Friday evening, May 18th. The subject of his talk was "What America Needs in Aeronautics." Admiral Peary's emphatic expressions in favor of a separate department for aeronautics in our military system met with enthusiastic approval from Chicago aviation enthusiasts. His utterance in favor of an aviation reserve which would permit of the enrollment of men from mechanical, but not necessarily educated classes, also met with hearty approval. Charles Dickinson, President of the Aero Club of Illinois, in emphasizing this latter point, indicated numerous instances where the gift of the birdman often had been found in men of comparatively little education.

New Duesenberg Plant

New York.—The Duesenberg Motors Corp. has filed plans for the construction of a plant in Elizabeth, N. J., for the manufacture of aeroplane engines for the Government. The plant will be in Newark Avenue and will cost $20,000. The company has been forced to seek larger quarters. It has been occupying a plan at Edgewater temporarily.

It is believed that the new plant will be the largest in the East, being one story, and employing more than 1,000 men. The company has bought 9½ acres of land in Elizabeth.

McCall White Resigns from Cadillac

Detroit.—D. McCall White, chief engineer of the Cadillac Motor Car Co., has resigned. No announcement has been made as yet regarding his successor. It has been reported that Mr. White has designed an aeroplane engine in which the Government is interested, and that this is the cause for his resignation. Mr. White was chief engineer of the Napier Motor Car Co. of England prior to his connection with the Cadillac company. For the past year he has been chairman of the Detroit section of the Society of Automotive Engineers, and he is a director of the Aero Club of Michigan.

Interested Army witnesses of the activities at one of the American training fields

Army students and instructors getting ready for the American offense in Europe

Washington University Has Course in Aeroplane Building

Seattle.—For the benefit of students of the University of Washington who desire to enter the aviation section of the signal corps, a course in aeroplane construction is being offered by J. W. Miller, assistant professor of civil engineering at the state university.

The series will continue throughout the rest of the present semester and will deal with the following subjects: Types of aeroplanes, monoplanes and multiplanes; aeroplane details; stability, static and dynamic essentials of design; flight and aeroplane instruments; the aviation section of the signal corps of the United States army, and the complete working details for the building of an aeroplane.

No credit is given for the work and there are no prerequisites. Persons outside the university may arrange to take the work.

Fay L. Faurote Addresses Buffalo Ad Club

Buffalo.—Fay L. Faurote, advertising manager of the Curtiss Aeroplane Company, addressed the Ad Club at a luncheon in the Hotel Iroquois recently and showed a series of slides that traced the history of aeroplane construction from the time when the idea of flying was conceived.

Mr. Faurote showed the various types of aeroplanes made in the last several years and the improvements effected in the modern machines.

Indianapolis University Arranges Course in Aeronautics

Indianapolis.—In response to the rapid progress which the science of aeronautics has made and to the interest which the present war has developed in the subject, the extension division of Indiana university announced that a short course of six lectures will be given in Indianapolis on aeronautics. The course will begin May 11 and continue for six weeks, with one lecture each week. The lectures probably will be given in the Chamber of Commerce building.

Tobias Dantzig, of the department of mathematics of Indiana university, will have charge of the course. He is a graduate of the University of Paris, and has taken a special course in the "Ecole Superieure d'Aeronautique" of Paris. Mr. Dantzig is giving a course similar to the one which he will give here for the recently organized Indiana university Aero Science Club at Bloomington.

U. S. Army Flier Killed on Border

El Paso, Tex.—Lieutenant Melchior Eberts, United States Army Aviation Corps, was killed May 15 by a fall with his aeroplane during a flight at Columbus, N. M., according to a telegram received at divisional headquarters here. Captain James L. Dunsworth, who was in the machine with Lieutenant Eberts, was injured, but will recover, his physician reported.

The aeroplane fell from a height of 1,500 feet. The accident was attributed to atmospheric conditions resulting from the altitude and the dryness of the region about Columbus, the machine having been caught in an air pocket.

Packard Aeronautic Activities

Detroit.—A variety of stories rearding the aeranautic activities of the Packard Motor Car Co. have been circulated, the latest being on a supposed high-speed plane that the Packard company was said to intend building. Aerial Age is able to state authoritatively that the Packard Motor Car Co. has given up the idea of making planes, as it is going to turn its entire attention in this department to the manufacture of aeroplane engines.

A group of aeronautic authorities at one of the aviation fields. Lieut.-Commander John H. Towers is shown in the center, wearing a derby hat, and Fay L. Faurote, chairman of the Censorship Committee of the Aircraft Manufacturers' Association

Pensacola News

The trial flights of the great Curtiss H-12 flying boat aroused much interest. Several very successful flights were made.

The new Navy dirigible—DN-1—which has been exciting the curiosity and straining the expectancy of the entire Station and of Pensacola for these many months, has taken its trial flights in the most approved manner. Sailing high over the Bay and the City, it was an object of admiration to all.

We note the transfer of Lieut. M. A. Mitcher to the U. S. S. "Huntington," where he is to take charge of the catapult and the aeronautic work. Lieut. Mitscher has been prominently connected with the engineering work at this Station, both as officer in charge of the machine shop in the trying days of the "North Carolina's" catapult installation, and later as Engineer Officer. Recently, as one of the Flying Instructors, he has spent many hours in the air. In view of the excellence of his past record, we feel safe in prophesying all success for Lieut. Mitscher in his new assignment.

A Hint on Landing

One of the little known dangers attending land flying is that the color of the landing field has its effect upon the machine. Land which is dark from being plowed or burned over will heat the air over it faster than will a field of stubble, the difference being due to the varying absorption and reflection of sunlight. A landing place which has an area of heated air above it is dangerous, as the air disturbance gives insecure support for the planes. One aviator told of attempting such a landing and being tossed upward by a warm current when he had almost reached the ground.

Naval Reserve F. C. News

Lieut. Edward O. McDonnell has been detailed as Naval Instructor in charge of Units Nos. 1 and 2, U. S. Naval Reserve Flying Corps. Beside the regular flying instruction, Lieut. McDonnell has instituted formation flying with six machines. A coastal flight from Palm Beach to Miami was planned for April 22d, but had to be called off on account of the inclement weather. All necessary precautions were taken in case of accident. Three automobiles and a motorcycle were to have convoyed the squadron down the coast, the local authorities having waived the speed laws for the occasion. At several points, motor boats were to have been stationed five miles off shore to render assistance if necessary, and to pick up messages which were to have been dropped from the planes in flight.

Flying hours are from six to ten a. m., and from three to six p. m. Between times, Lieut. McDonnell gives lectures on theoretical aeronautics, seamanship, navigation and naval etiquette. Instruction is also given in radio and in the different methods of visual signalling.

Acieral Metal

Acieral is a new metal, containing 97% aluminum, introduced and manufactured by the Acieral Company of America, 26 Cortlandt Street, New York City, at their Newark N. J. foundry. In importance the creation of Acieral takes rank at once among the foremost of human achievements. The production of steel with its marvelous strength was a triumph, the value of which has never yet been computed. The reduction of aluminum with its astonishing lightness in commercial quantities was a stroke of genius almost without parallel. But steel is heavy; aluminum is weak. The creation of ACIERAL, a chemical union combining the strength of steel with the lightness of aluminum—who shall say that this does not mark the crowning achievement of the metallurgist's art?—the discovery of a universal metal. The uses to which this metal can be put are limitless, and on account of its strength and lightness and no-corrosive qualities it is particularly suitable for use in the construction of all classes of aircraft. It is silver white in color, is said not to oxidize either in air or water, fresh or salt, has a specific gravity of 2.82 and a melting point of 1382 deg. Fahrenheit. Its tensile strength in castings is 22.000/28.000 lbs. per square inch with elongation of from 0.5 to 5 per cent. In rods and sheets the tensile strength runs from 28.000 to 64.000 lbs. per square inch and when tempered to over 72.000. Reduction of area: from 10 to 35% according to specification. It can be sand cast, die cast, hot and cold forged, annealed, drawn, stamped, hardened by temper and soldered, etc.

It is also claimed that it withstands well the action of all acids, hot or cold, except hydrochloric.

Acieral is furnished in the form of ingots, castings, plates, rods, wires and tubes.

The present plant of the Acieral Company of America has a daily capacity of 10 tons and has now been in operation for about two months.

First Aero Corps to France Soon

Inquiries at the Aero Club of America regarding the statement of the French War Minister, M. Paul Painleve, in which he says that the United States is sending airmen to France, brought out the fact that for the past two days the Aero Club of America has been the recruiting office for the personnel of the First Reserve Aero Squadron which is to be sent to France as soon as the recruiting is completed.

The First Reserve Aero Squadron is to be commanded by reserve aviators who were trained at Governors Island and Mineola during the past year, including Major Raynal C. Bolling, Capt. Philip A. Carroll, Capt. James E. Miller, First Lieut. Daniel R. Noyes, Frederick T. Blakeman, Charles Reed, Hobart A. H. Baker and Edwin M. Post, Jr.

A few days ago the Aero Club of America called for mechanics to make up the enlisted personnel of this aero squadron, for which are needed 154 men, and it is desired to get as many expert mechanics as possible. There was quite a substantial response to the call, but as it is desired to have mostly expert mechanics, the Club is still calling for men with expert knowledge of gasoline engines. The men who will go to France with this First Aero Squadron will, of course, make history, and they will have the opportunity of getting a special course of training in gasoline engines and the mechanical part of aeronautics under the very best French experts. Their pay is from $36 to $75 a month, with 20 per cent additional for foreign service, with all clothing, food and transportation in addition.

The War Department and the Aero Club authorities have been receiving many applications from aviators, military and reserve, who would like to go to France; in fact, the applications are so numerous that several aero squadrons could be formed right away to go to France. There is also a large number of applications from college men from all over the country who would like to take aviation training immediately to join aero corps going to France.

Prominent Americans Join French Aero Corps

Eight young Americans of prominent families have left for a port in France to join the Lafayette Flying Corps, the famous organization of picked Americans, of which William Thaw is a member. Five of them are graduates of Harvard and Princeton Universities, and they and their three associates were selected from among 100 applicants who were eager to fight in the air in France for the cause of the United States and her Allies. They are:

William Henry Meeker, of New York, Harvard, A. B., 1917, and formerly member of the editorial staff of The Crimson, Harvard's daily newspaper.

Vernon Booth, Jr., of New York, Harvard, A. B., 1913, who left a law practice in the city to join the flying squadron.

Cyrus F. Chamberlain, of Minneapolis, Minn., Princeton, A. B., 1915, son of F. A. Chamberlain, head of the First and Security National Bank of Minneapolis.

Benjamin Stuart Walcott, Princeton, 1917, son of Charles D. Walcott, Secretary of the Smithsonian Institution, Washington, D. C.

Samuel W. Wiggins, Cincinnati, Harvard, A. B., 1915, and member of a banking firm.

Ted Ford, member of a prominent Washington, D. C. family.

Roger Harvey Clapp, Salt Lake City.

Ferchar I. Ferguson, of New York, who drove an American Red Cross ambulance behind the Allies' front near Dunkirk for nine months in 1915. He is related to the Armours, the packers.

Each of the eight was examined for "air sense" and for general ability to handle a battle plane before being accepted. Meeker took daily practice for three weeks in the Thomas Morse Aviation School and proved himself peculiarly fitted for the work. Walcott flew with the late Victor Carlstrom, who recommended him for the service.

On arriving at Paris the aviators will present their credentials to Dr. E. L. Gross, the director of the corps, and after being examined and trained they will go to the front with Lieutenant Thaw and Adjutant Raoul Lufbery.

New Sub-Committees of the Council of National Defense

The following new sub-committees of the Council of National Defense with their personnel were announced on May 9. The steel sub-committee consists of Judge E. H. Gary, James A. Farrell, Charles M. Schwab, James A. Burden, E. A. C. Clarke, president Lackawanna Steel Co.; Alva C. Dinkey, of the Midvale Co., and W. L. King and John A. Topping, of the Republic Steel Co. A. C. Bedford, president of the Standard Oil Company, heads the sub-committee on oil. Chairmen of other committees are Horatio S. Rubens, director of the U. S. Industrial Alcohol Co., alcohol; Arthur V. Davis, aluminum; Charles F. Brooker, brass; W. H. Childs, coal tar by-products; R. H. Dowmen, lumber; Clinton H. Crane, lead; L. W. Kingslay, mica; Ambros Monell, nickel; H. Stuart Hotchkiss, rubber; Henry Whinton, sulphur, and Jacob F. Brown, wool.

Army and Navy News

The following-named officers of the Aviation Section, Signal Officers' Reserve Corps, are assigned to active duty; they will proceed to Governors Island, N. Y., and report in person to the commanding general, Eastern Department, for duty in connection with the organization of the First Reserve Aero Squadron, Signal Corps: Maj. Raynal C. Bolling, Capt. Philip A. Carroll, Capt. James E. Miller, First Lieut. Daniel R. Noyes, First Lieut. Frederick T. Blakeman, First Lieut. Charles Reed, First Lieut. Hobart A. H. Baker, First Lieut. Edwin M. Post, Jr.,

Under the provisions of paragraph 38, Regulations for the Enlisted Reserve Corps, the following sergeants of the Signal Enlisted Reserve Corps, now on duty at the Curtiss Aviation School, Miami, Fla., will be discharged by the Chief Signal Officer of the Army, by reason of their services being no longer required: Robert Matter, Stanton T. Vanderbilt, James W. Junkin, Ben T. Myers, Russell MacDonald, William H. DeWald, William B. Rodgers, Jr., Dunn K. Steele, Wallace D. Culbertson, Allyn R. Jennings.

First Lieut. Fred A. Post, Aviation Section, Signal Officers' Reserve Corps, is assigned to active duty. He will proceed to Fort Omaha, Nebr., and report in person to the commanding officer, United States Army balloon school at that place, for duty.

Capt. Virginius E. Clark, junior military aviator, Signal Corps, will proceed to Detroit, Mich., for temporary duty in connection with aeronautics of the Army, and upon the completion of this duty will return to his proper station in this city.

Major Frank P. Lahm, junior military aviator, S. C., from San Diego, Cal., to Fort Omaha, Neb., and assume command of the U. S. Army Balloon School. (May 9, War D.)

Sick leave one month to Capt. Benjamin G. Weir, junior military aviator, S. C. (May, 10, War D.)

Sergts. 1st Class Harry V. Hand and Clarence H. Maranville, S. C., to Essington, Pa., for duty. (May 8, War D.)

Sergt. 1st Class Alexander B. Culp, S. C., Fort Sam Houston, Texas, to Buffalo, N. Y., for not to exceed three months for instruction at the Curtiss Aeroplane Company. (May 9, War D.)

American height flying records were broken at San Diego, Cal., on May 11, by Lieut. W. A. Robertson, U. S. A., junior military aviator at the North Island training school, who reached a height of about 16,400 feet. The American record, 16,335 feet, had been held by Victor Carlstrom, who was killed in a flight at Newport News, Va., on May 9. Lieutenant Robertson had as a passenger Lieut. C. K. Rhinehardt, U. S. A. They used a 300-horsepower battleplane. Zero temperature prevailed above the 16,000-foot level and both aviators suffered intensely from the cold.

The Southern Department has been authorized to take steps for the establishment in San Antonio of the largest field yet opened by the Government. An option has been secured on 1,000 acres of land located about six miles south of the city on the Frio Road and this will be purchased by the War Department. Major Gen. J. J. Pershing was instructed to organize two more aero squadrons in San Antonio and these, with the officers, men and machines now stationed at the aviation field east of Camp Wilson, will be transferred to the new field. The present aviation field will be turned over to the remount station at Fort Sam Houston and the hangars dismantled and removed to the new field. Many recruits for the Aviation Service are being received from the East, according to Colonel Barnum, Chief of Staff, and the officers at the present field will be divided up among the new squadrons to be formed. Further recruiting in this branch is being carried on daily and sufficient men and officers for the greater air arm of the Department are assurred.

The following officers of S. O. R. C. to active duty: Major G. M. York to station in New York, N. Y.; 1st Lieut. J. R. Whitehead to station in New York, N. Y., as assistant to the signal officer of Eastern Department; 1st Lieut. R. R. Whiteside to San Fransisco, Cal., for duty as assistant to signal officer of Western Department. (May 12, War D.)

Sick leave one month to 1st Lieut. Birdseye B. Lewis, S. O. R. C., Base Hospital No. 1, Fort Sam Houston, Texas. (April 27, S. D.)

The following officers of the Aviation Section, S. O. R. C. to active duty at Governors Island, N. Y., for duty in connection with the organization of the 1st Reserve Aero Squadron, Signal Corps; Major Raynal C. Bolling, Capt. Philip A. Carroll, Capt. James E. Miller, 1st Lieuts. Daniel R. Noyes, Frederick T. Blakeman, Charles Reed, Hobart A. H. Baker and Edwin M. Post, jr. (May 10, War D.)

First Lieut. Fred A. Post, Aviation Section, S. O. R. C., to active duty at Fort Omaha, Neb. (May 12, War D.)

First Lieut. Edward R. Kenneson, Aviation Section, S. O. R. C., to active duty at Princeton, N. J.) (May 9, War D.)

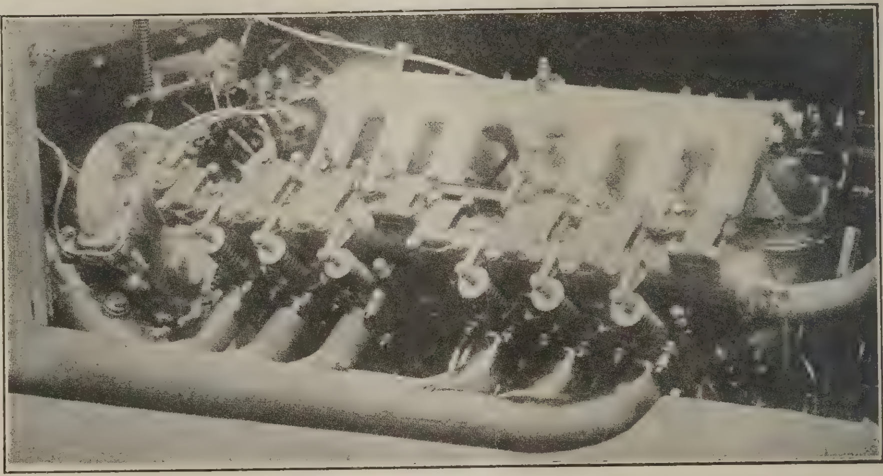
THE MECHANICAL DEVELOPMENT OF AVIATION

By NEIL MacCOULL, M. E.*

PART III

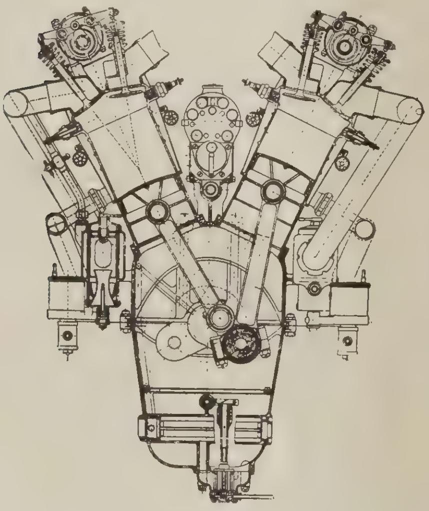
(*Continued from page* 334)



An Experimental Engine Built by the Packard Motor Car Co.

No official confirmation has been received so far of any Mercedes engine with more than six cylinders except the one shown, which was built for Zeppelins; but the modern Zeppelins do not use this type of engine. Instead they use six cylinder vertical engines of 00 H. P. at 1,200 r. p. m., the cylinders being about 6 inches in diameter with a 7½ inch stroke. The most interesting feature of these engines is the use of five valves in each cylinder head; two intake and three exhaust. One rocker arm operates each set, from a push rod operated by cam-shafts, of which there are two, located on either side of the crank case. The use of so many valves is food for much thought. It seems that exhaust valves give about as much trouble as any part of an aeroplane engine except the spark plugs, and this is due to failure by heat. Small valves are much easier to keep cool than large ones, and it may be depended upon it that German designers would not have gone to this complication if the results had not been worth it.

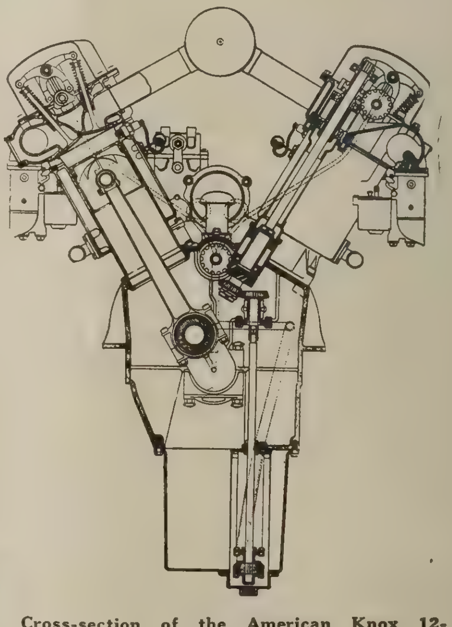
One of the first American engines to follow the lead of the Mercedes as to type was the Hall Scott. The cylinders of this engine, while individual as in the latest Mercedes, are cast with integral water jackets, giving a more rugged though heavier construction. The intake manifold and double jet carburetor are water and oil jacketed, the oil jacketing not only warming the carbutetor, but cooling the oil. The valve mechanism of this engine is very nicely worked out. It is the middle one shown on Fig 13, the one to the left being that of the Mercedes. The cam-shaft housing is cast of aluminum and may be detached as a unit from the cylinders without disturbing the valve rockers. Notice the felt washers on each side of the rockers where they pass through the housing; and the effective means taken to lock the adjusting screws on the split ends of the rockers. The tube shown in the cylinder casting between the valve passages is the water outlet, the tube passing through all cylinders with openings cut in it opposite the exhaust passages so as to secure good circulation around these hot parts. A noticeable characteristic of all valve mechanisms of this type is that the valves can be removed only by taking them out through the cylinders.



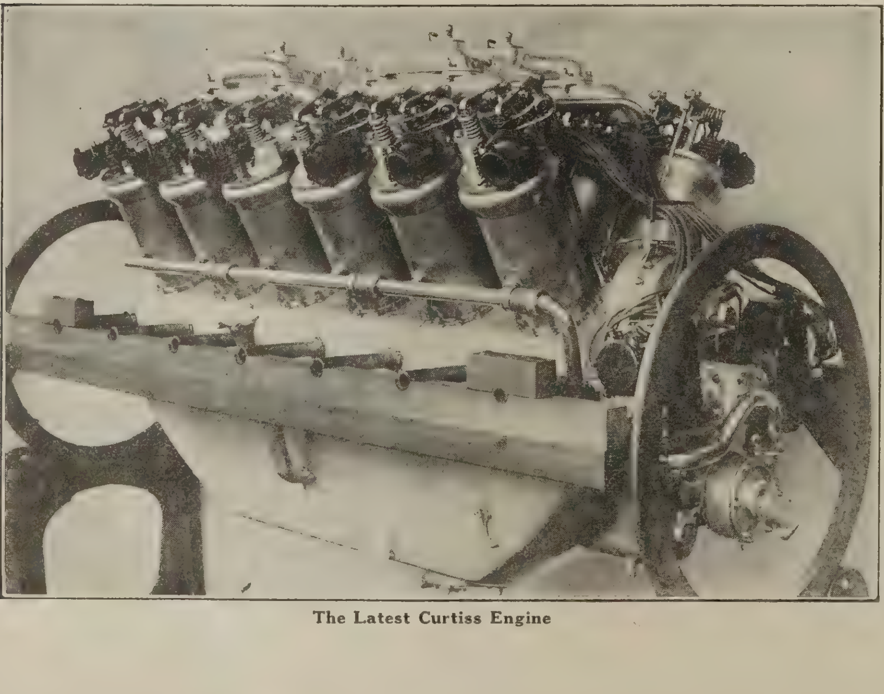
Cross-section of a 12-Cylinder Water-cooled Renault

The two points of chief interest shown in the section of the Mercedes valves, are the method of building the cylinders up by welding, and the location of the rocker fulcrum so as to give the valve 50 per cent greater lift than its cam. It is a small detail, but one which means a good deal in results.

The valve construction shown to the right is that of the Wisconsin engine, which will be described later. It will be seen to be quite similar to the other two in general design. There is a little lip on the rockers just under their fulcrums which should not be overlooked. Its purpose is to drain off the oil which would tend to leak out of the housing. The passage in the lower part of the housing acts as a return for the surplus oil fed to the cam-shaft.



Cross-section of the American Knox 12-Cylinder Engine



The Latest Curtiss Engine

Another six cylinder engine of this general type is the Christofferson. The rocker arms are of different lengths, as in the Mercedes, but the whole valve mechanism, including springs, is enclosed. This makes a very neat arrangement, and one that assures excellent lubrication of these parts, but it is doubtful if it is a wise policy to enclose the springs. It has been found very advantageous with many engines to allow the valve springs to project through the aeroplane hood so as to be sure that they will be well cooled. One of the most interesting features of this engine is the ring type of intake manifold, which allows each cylinder to draw its fuel mixture from two directions, and would appear to give equal distribution to every cylinder without resorting to two carburetors. At the bottom of the crank-case can be seen the oil radiator which is beginning to be considered so valuable lower part of the crank case when it is removed.

The experimental engine built by the Packard Motor Car Co., which is shown in Fig. 16, is worthy of attention because it has been developed under intimate knowledge of requirements at the battle front. It is a twelve

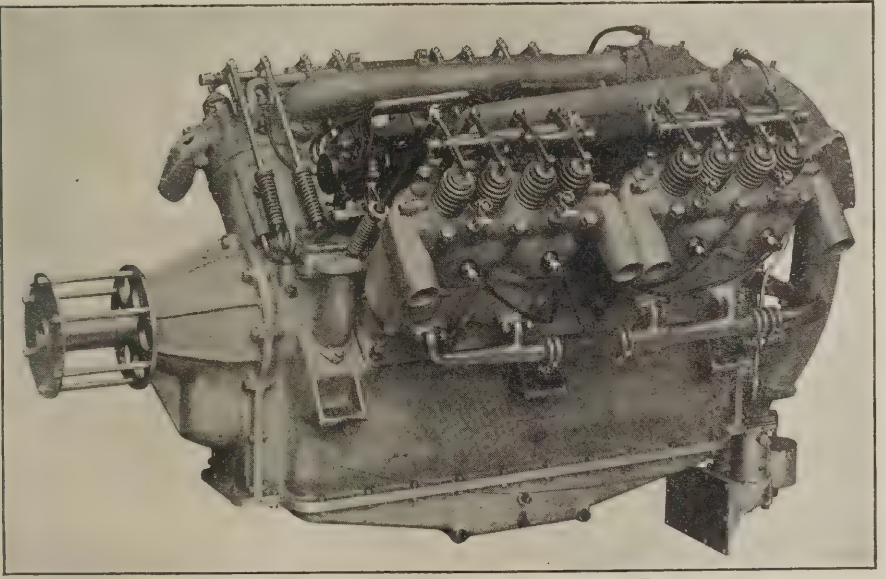
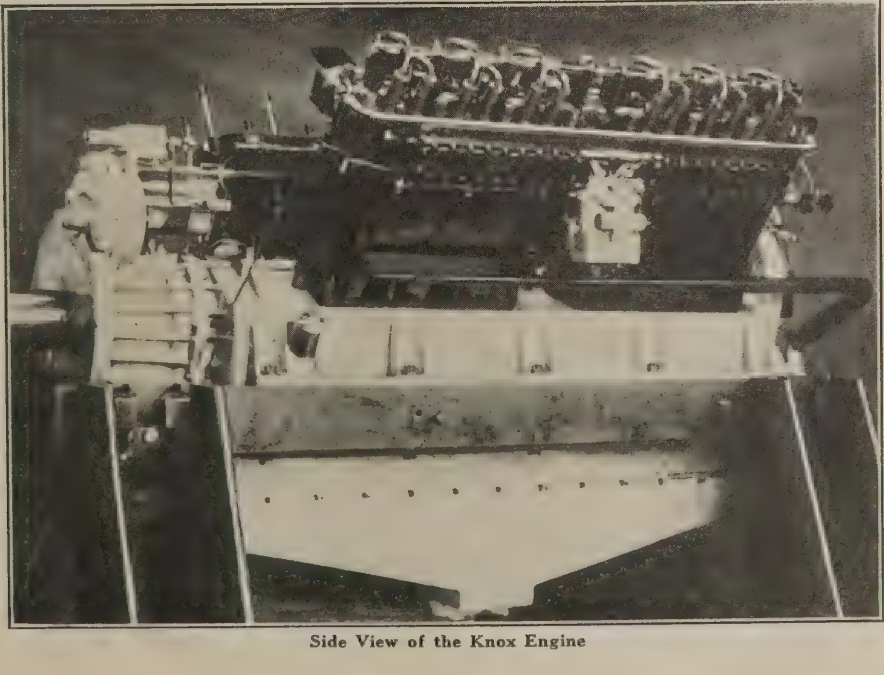
A New Sunbeam Engine With Two Cam-shafts for Each Row of Cylinders



The New Sturtevant Eight-cylinder "Aluminum" Engine



Side View of the Knox Engine

cylinder V-type engine with 60° between rows of cylinders. The intake manifolds, of which there are two, are the first departure from usual practice which meets one's eye. They are designed with the idea of supplying each cylinder from a large header in which the gas velocity is so low that every cylinder has almost the same pressure drop from the carburetor which is located in the middle. One would not expect very good carburetion, however, unless the fuel is perfectly vaporized, a condition not often realized, particularly at the extreme cold of high altitudes. A very clever design has been made use of in taking the valve rockers through the cam-shaft housings. The fulcrum takes the form of a short shaft with one of the arms on each end. The bearing of this fulcrum makes a comparatively oil-tight joint. The cam-shafts are driven by trains of spur gears instead of by lay-shafts and bevel gears.

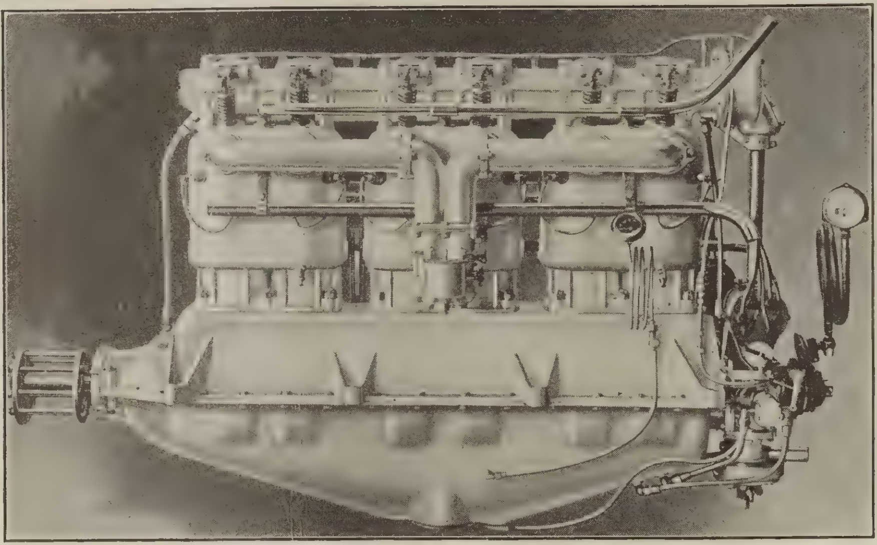
Fig. 17 shows a twelve cylinder engine which is the latest production of the Curtiss industries, and bears ear marks which are characteristically "Curtiss." In fact, the cylinders and valve mechanism are practically identical even in size with those used on the 8-cylinder 160 horsepower model. It is rated at 250 horsepower. The cylinders are made of high carbon steel drop forgings, with monel metal jackets brazed on. All valves are operated through rockers and push rods from a single cam-shaft in the crank-case, like the valve drive of the Buick automobile engine. The push rods, with the intake manifolds and their four carburetors, together with the 24 cables for double ignition certainly make an imposing collection between the rows of cylinders.

One of the well known British engines is the Sunbeam, which is shown in Fig. 18. In this design the manufacturers have finally discarded the L-head cylinders which have characterized all previous Sunbeam aeroplane engines, and have made a radical departure from usual valve mechanisms. There are four valves to each cylinder, two intake and two exhaust, and these valves are operated by two overhead cam-shafts to each row of cylinders, one shaft for the inlet valves and the other for the exhaust. The cam-shafts are driven by trains of spun gears. This type of valve mechanism has been used on Sunbeam racing automobiles for a number of years. Notice that two carburetors are used on each row of cylinders, and that a compressed air starting system is used as evidenced by the distributing valve at the end of the exhaust cam-shaft just to the left of the magnetos. The propeller is driven at a lower speed than the engine by means of gearing.

The description of the following two engines are particularly interesting because they have been brought out very recently by manufacturers who have had considerable experience in building engines for war service, and involve changes from their usual practice which have been found advantageous after trial at the front. The first is the Sturtevant. For years the B. F. Sturtevant Co. has been a strong advocate of L-head cylinders and has apparently had much success with them, but they have finally given in to the overhead type. The cylinders and heads are cast of aluminum and provided with steel liners and iron valve seats which are cast in the aluminum. The use of detachable cylinder heads is quite an innovation in the aeroplane world and shows a desire to make accessibility a stronger factor than is now customary. Like the great majority of aeroplane and automobile racing engines, aluminum pistons are used. When referring to aluminum, I mean aluminum alloy, of course, for pure aluminum is no more like its alloys than iron is like alloy steel, and in its unalloyed state would be absolutely worthless in this service. This engine is of the high speed type with geared down propeller, the engine running normally at 2,000 r. p. m.

The engine shown in Fig. 20 is the new water-cooled Renault of 220 horsepower. For years the manufacturers of this engine have supported the twelve cylinder V-type engine with forced draft air cooling. Now they have adopted water. They have also dropped the high speed feature with geared down propeller shaft, and the valve mechanism with cam-shaft in the crank-case—features which have always been characteristic of Renault aeroplane engines. The valve mechanism is now strikingly like that of the Mercedes. Use is made of two double carburetors and four six cylinder manetos. Notice particularly the connecting rod construction with one rod pinned to a boss on the rod opposite to it. This is used on no other engine except the new Wisconsin "twelve," though it must have given good results because Renault has used it for so many years.

In Fig. 20A is shown a section of a 300 horsepower engine just brought out by the Springfield Motors Co., and shows an innovation in aeroplane engine valve mechanism. Not only are the rockers unusually compact because of being bell cranks, but each arm which operates the valves is forked so as to open two valves from a single cam. There are two intake and two exhaust valves to each cylinder which feature very considerably reduces the



Carburetor Side of the Wisconsin Engine

stresses in these parts on account of lower inertia forces, and results in much greater reliability and longer life. The cylinders are cast of aluminum with cast iron liners ⅛-inch thick. The pistons are of aluminum, of course, and so are the cylinder heads, the iron valve seats being cast integral. The oil pump at the bottom of the crank-case is shown with its drive from bevel gears on the cam-shaft lay-shafts which are driven by spiral gears.

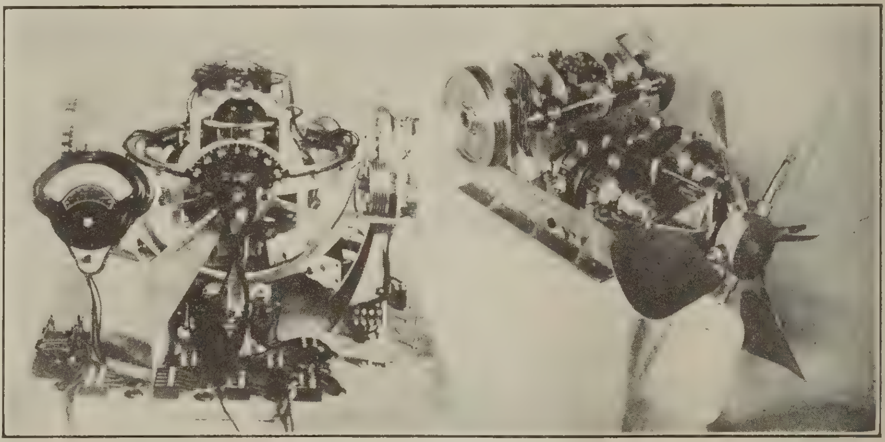
Fig. 21 shows the general appearance of the engine with the cover for the valve mechanism removed, showing the forked valve rockers. The double carburetor bolted to the cylinder castings shows how intake pipes have been eliminated by casting the manifolds integral with the cylinders, where they are water jacketed. The housing of the reduction gear for the propeller shaft is very prominent at the left, the engine being designed for 1,600 r. p. m. and the propeller 1,140 r. p. m. Since the propeller is 14 feet in diameter it can be understood why it is not run any faster than this if any one checks up the speed of the tips of the wooden blades. It amounts to more than 830 feet per second. An outstanding feature of this engine is that it is an assembly of complete units. The cylinder head with cam-shaft and all valve parts makes one complete assembly which is easily detachable without disturbing any of its parts, and the reduction gear and electric starting motor with its gears, makes another.

The Wisconsin engine has been brought out recently by the same company that manufactured the engines for the famous Stutz racing automobiles, and embodies many of their best features. It is another instance of the intimate relations existing between aeronautical and racing automobile engines. The cylinders and pistons are of aluminum, and of course the crank-case is. The cylinders have hardened steel liners 1/16 inch thick, and the iron valve seats are cast integral with the aluminum. A cross section of the valve mechanism was shown in Fig. 13 with the Mercedes and Hall Scott valves. Two magnetos and a double jet carburetor are used, of course.

The longitudinal section of the engine shows details of the lay-shaft drive for the cam-shaft. The magnetos are driven by spiral gears in this design. Nothing is contained in the lower part of the crank case except the usual oil filters. The twelve cylinder engine is made up of two sets of the cylinders and valve mechanisms of the six cylinder model, and is rated at 280 horse power. Instead of driving the cam-shaft by lay shafts and bevel gears, two trains of spur gears are used. As mentioned before, the connecting rods of one side of the engine hinge to bosses on the rods of the other side, as is characteristic of the Renault. Four six-cylinder magnetos are arranged across the front of the engine. Provision is made on most of these large engines for mechanical or electric starters, and the electric generators for searchlights and wireless sets which are often carried.

So far the development of the aeroplane power plant has been dealt with almost entirely, but engines do not begin to cover all the mechanical parts of modern aeroplanes. The time is so limited that I can merely mention a few of the other parts which this new science is developing. Mechanical starters alone make quite a study, and beside compressed air distributors and air engines include even small gasoline engines of about 4 horsepower which weigh but 23 pounds with their own magnetos and carburetors. Then there is a special gun of large bore for aeroplane use, which fires out of both ends at the same time in order to eliminate the recoil. There is a score or more of special instruments which have been devised to indicate the speed, angle of incidence, drift, altitude and other factors necessary for the navigation of an aeroplane Mechanical stabilezers also have been developed. Fig. 24 shows two of the units of the Sperry system, the one at the left being the gyro proper and the one at the right the servo motor which operates the controls. Four small gyroscopes driven by three phase current maintain a constant horizontal reference plane, and motion of the aeroplane about this plane closes electrical contacts which operate clutches in the servo-motor. The windmill of the servo-motor which is exposed to the relative motion of the air, is the source of power used in operating the controls. When the windmill reaches a predetermined speed the blades fly outward, at the same time turning so as to reduce their pitch, thus holding a constant speed. The magnetic clutches when energized connect the windmill to worm gearing, which drives the drums over which the control wires are wrapped. With this stabilizer it has been shown possible for the aviator to leave his controls and walk out on one of the wings while in full flights.

In closing it is well to call attention to the fact that progress in the mechanical engineering of aviation is so rapid at present that the designs shown in this article as the last word in the art will probably be out of date this time next year and will be merely of interest tical lay-shaft. The drive of the centrifugal as historical stepping-stones.



Two of the Units of the Sperry Aeroplane Stabilizer

The Flying Machine

The Flying Machine from an Engineering Standpoint. By F. W. Lanchester. (Constable & Co. 4*s.* 6*d.* net.)

"The author's 'James Forrest' lecture, now presented in book form, was delivered before the Institution of Civil Engineers three months prior to the outbreak of war; it constituted an attempt to epitomize the state of scientific aerodynamic knowledge, and of the technical art of aeroplane construction at that time. . . .

"The present republication of the lecture has been undertaken in order to meet the many applications for copies, which have been greatly in excess of those available. . . .

"Incidentally, the author has taken the opportunity of republishing a paper which was contributed by him to the 1915 International Engineering Congress, San Francisco, Cal. ('Concerning the Theory of Sustentation and Expenditure of Power in Flight')."

The above quotations from the preface serve to show the aim of this book, and those who are familiar with Mr. Lanchester's outlook will not need to be told that a detailed discussion of it cannot be undertaken in a short notice. Those who are not familiar with Mr. Lanchester's wide range of vision and unconventional treatment of aeronautical problems have undoubtedly missed much that is stimulating and suggestive, but not everyone will be ready to concede that because he touched on certain aspects of the matter years ago, therefore all subsequent work on those aspects is founded on the Lanchester basis. It should be said at once that no specific claim of this sort is here made; it is, however, implied in much that Mr. Lanchester has said and written. This is quite apart from the points on which Mr. Lanchester still finds little support, such, for example, as his "cyclic" theory of sustentation, which he rightly classes as still a matter of controversy. It may be that, as Mr. Lanchester clearly anticipates, this theory will form the basis of the future aerodynamical theory of sustentation. He is certain of its truth, and has certainly done his best to persuade others of the value of the revelation which came to him so long ago as 1894. That so long a period has elapsed without success attending his crusade may be interpreted how one pleases; it, at any rate, gives the present reviewer a pleasing sense of companionship in his attitude of "not proven," while not preventing him from recognizing the value of Mr. Lanchester's contributions to aeronautical science.

California Branch of S. K. F. Organized

In order to more readily supply the rapidly increasing demand for S. K. F. bearings on the Pacific Coast, the S. K. F. Ball Bearing Company of California, Inc., has been organized for the sale of these well known self-aligning radial and thrust ball bearings.

The main office of this company, under the direction of Mr. A. M. MacLaren, has been opened in San Francisco at No. 341 Larkin street, and at this office a large and assorted stock of bearings will be carried. The engineering services of the company will also be available by addressing this office. The company's engineers will be glad to investigate conditions and assist the users of ball bearings, present and prospective, in determining the best means of reducing friction losses and selecting an equipment.

MILITARY OBSERVATION BALLOONS

By Major C. DeF. CHANDLER, Signal Corps

WHEN a few short years ago the aeroplane proved to be a successful invention, and the attention of practically all students of aeronautics was drawn to its development for military purposes, interest in the captive balloon as a means of observation waned, not only in the United States, but abroad. In our case, the lack of sufficient appropriations for the aeronautical service of our army was also largely responsible for our failure to develop this valuable auxiliary.

The present war in Europe has demonstrated that the aeroplane, while of the greatest value for aerial reconnaissance, is not able to replace the captive balloon. Though it possesses the advantage of mobility and the ability to pass directly over the positions to be observed, the results of its reconnaissance must be reported by radiotelegraphy, by special codes of visual signals, or by a return to the starting point to drop written messages.

The great advantage of the captive balloon is derived from the fact that the observer is constantly in direct telephonic communication with the artillery commanders in his vicinity; constant and thorough inspection of the enemy's positions with the aid of powerful glasses and telescopes reveals every movement of bodies of troops or anything new that has appeared during the previous night, and the targets thus presented can be immediately taken under fire. Continuous and searching observation of the same sector enables an observer to note even slight changes in the color of the earth and to make important deductions therefrom. Changes in trench construction can thus be easily detected.

One observer on the western battle front in France states that he was able to count twenty-six balloons in sight at one time; this is convincing testimony of their extensive use. It is an interesting development of the present war that battle type aeroplanes are assigned for the protection of the captive balloons and for this purpose cruise about at a height of several thousand feet above the balloon ready to swoop down upon any enemy aeroplanes that attempt to destroy it.

The spherical type of captive balloon has been abandoned in favor of the kite type, often referred to as "sausage" or "drachen" (German for sausage) balloon, since the latter type has much greater steadiness in winds; the pressure of the moving air against the under side of the balloon holds it steady in the same manner as in the case of the common paper kite.

The kite balloon is fitted with a tail consisting of several conical canvas cups, to assist in maintaining its stability, with the same result as is secured by affixing a tail to the toy kite.

In Europe the observation balloons are placed about four miles in rear of the line of trenches, and are separated by intervals of approximately six miles. The altitude at which they are held is dependent upon the atmospheric conditions and upon the distance of the enemy's artillery. They are usually sent up at daylight, and remain in the air until dark, being drawn down every few hours to change observers. Occasionally they remain up at night, and it is frequently found that enemy guns that are not visible by daylight may be located at night by their flashes. Even after dark it has been found that observers who have studied every feature of the ground for days are able to see enough to fix accurately the position of the flashes. The strain of constant observation with high power glasses or telescopes makes it advisable to change the observers at frequent intervals.

It is customary to have two officers in the car of the balloon, and they are connected with the ground by telephone. One method is to have an insulated telephone wire in the center of the cable which holds the balloon; another method is to drop a strong, light-weight wire from the basket of the balloon to connect with the telephone circuits directly underneath. In both cases the steel wires of the holding cable serve to complete the electric circuit for the telephones.

Balloon companies are provided with telephone switchboards so that the observer in the basket can communicate directly with any battery or higher artillery commander in his vicinity.

Buildings, hills, or specially constructed towers concealed by trees are frequently utilized in conjunction with captive balloons to provide an auxiliary observing station, so that the two may serve as the end stations of a base line for the accurate location of targets. In some cases another balloon is used as the second observing station.

It has been learned that at the beginning of the war various special codes of signals were experimented with for the purpose of enabling observers to report the error in the fall of shots, but these have been discontinued in favor of the brief announcement of "over," "short," "right," and "left." Perhaps this simplification is largely due to the accuracy with which the prospective target is first located by means of the two observing stations on the base line.

For service with the mobile army it was customary in Europe before the war to have highly trained balloon companies, able to inflate a balloon and have it, with its observers, several thousand feet in the air in about twenty minutes after the organization had halted; this speed was attained by using compressed hydrogen carried in special vehicles. The information of three or more years ago indicated that the peace strength of the balloon companies in Europe averaged about sixty men. The arduous and continuous service that has been required during the war has necessitated an increase in the number, there being at the present time in some cases 160 officers and men assigned to one kite balloon; this number provides for three reliefs for the captive balloon, the observation tower personnel, the telephone switchboard operators, and details for the manufacture of hydrogen.

Since the service along the western battle front has been in the nature of siege warfare, it has been practicable to supply hydrogen from portable field generators, instead of furnishing it compressed in cylinders.

The average capacity of the kite balloon is 28,000 cubic feet. There is continuous loss of hydrogen due to leakage through the fabric and to losses from expansion at high altitudes; these losses are ordinarily replaced at night. A common method of replacing gas is to fill small balloons called "nurses" at the nearest field generating plant; a small detachment of men can easily conduct this supply balloon to the hangar and transfer hydrogen from the "nurse" to the captive balloon as it may be required.

The most modern type of windlass for holding captive balloons consists of a winding drum constructed on a motor truck, taking power from the truck engine.

Whenever enemy aircraft attempt to destroy a captive balloon, it is customary to haul it down rapidly or to keep it moving around the field, to lessen the chances of its being hit. The moving is often done by using twenty-five or more men, each having a rope attached to a snatch block, through which the cable is passed. These men then walk to various points in the field, and their movement changes the position of the balloon not only horizontally but vertically as well.

Captive balloons are occasionally destroyed by incendiary bullets, arrows, or bombs dropped by aviators. Destruction in this manner is not necessarily fatal to the observers, as they are usually provided with parachutes attached to safety belts, which permit their safe descent to the ground.

About eight years ago, while Fort Omaha was garrisoned by signal corps troops only, a large balloon hangar was constructed at that point, together with a plant for generating hydrogen by the electrolysis of water and the machinery for compressing the gas. After its completion, the equipment was used for about two years for free and captive balloon instruction, but its employment for this purpose was later discontinued for the reasons previously given.

The U. S. Army Balloon School is now being established at Fort Omaha, all old serviceable equipment being used and much new material of every kind being added. It will not be long before the first balloon company will have everything that is needed, of the most modern type, including specially designed motor trucks for carrying compressed hydrogen.

In addition to organizing and equipping balloon companies for service with the mobile army, the school will probably be called upon to train officers and men in the handling of captive balloons at coast fortifications.

In case the cable holding a captive balloon should break, it then becomes necessary for the observer to descend and land in the same manner as in manœuvring the ordinary free balloon, for which reason an essential part of the preliminary training of students at the Balloon School will consist of the navigation of free balloons and qualifying as pilots thereof.

A tentative plan for the organization and equipment of balloon companies and battalions has been prepared, which will be tried practically at Fort Omaha before action is taken with a view to its official adoption. In order to reduce the impedimenta of balloon companies without impairment of their mobility, it is probable that field hydrogen generators and compressors will be carried only by one supply company in each balloon battalion.

There are several types of hydrogen generators suitable for field service, all of which should be thoroughly tried before the adoption of any one type or method. There is need also of larger types of generators and compressing machinery installed in railroad cars, which may be placed at the nearest rail points to the balloon companies as a refilling station for hydrogen cylinders.

Observation balloons are necessary for both field and coast artillery, but the mobile balloon companies are principally for the service of the field artillery. In Europe the observers are almost without exception field artillery officers, and it is natural that such should be the case in view of their training and experience in the location of targets and the observation of fire. It is therefore hoped that the field artillery officers of our army will become interested in this new auxiliary to their arm of the service.

In time of peace, details to the Balloon School, like those to the Aviation Schools, are made only upon the application of the officers through military channels. A physical examination, similar to that prescribed for applicants for aviation duty, is required. The student officers for the Balloon School are not, however, limited as to age and grade. Some field officers will be needed for administrative duties with the balloon division of the Aviation Section, and in order to be fully qualified for such positions they should be graduates of the Balloon School.

THE COURSE OF TRAINING AT THE U. S. ARMY BALLOON SCHOOL

The course of training at the Army Balloon School, at Fort Omaha, in which Major Chandler is in charge, is both practical and theoretical, and so arranged that the practical instruction has preference at all times when weather conditions are suitable.

Whenever high winds or rain interfere with the outdoor training the classroom instruction is held and consists principally of conferences. The instructor covers the subject thoroughly and students are expected to ask questions and join freely in discussion. Practical instruction in the measurement of specific gravity of gases, testing and adjustment of instruments and similar laboratory indoor work is conducted when weather conditions outside are unfavorable.

A number of officers of the Regular Army and Reserve Corps are undergoing practical training, and the school is also designing and trying out new types of field equipment of all kinds. Leo Stevens is in charge of the practical instruction of pilots and Major Hersey is instructor for the theoretical and classroom work, meteorology, etc. Upon completion of the course the students will at once be assigned with organized balloon companies for the mobile army, and for the installation and operation of observation balloons at coast defenses.

An outline of the course follows:

Practical Instruction

Generation and compression of hydrogen.

Hydraulic testing of gas cylinders.

Spreading envelopes and assembling parts of free and captive balloons.

Inflation of balloons.

Balancing free balloons.

Use of ballast and balloon instruments while on voyages.

Selection of landing spots and drag-roping.

Deflation by valve and rip panel.

Folding, packing and shipment of balloons.

Replacing of rip panel, repairs and inspection of envelope and net.

Qualification as balloon pilot according to F. A. I. Rules.

Testing of cordage and fabric for breaking strength.

Testing of fabric for permeability to gases.

Practical handling of captive balloon windlass.

Filling kite balloons rapidly from cylinders of compressed hydrogen.

Motor truck operation and maintenance.

Determining course and position of free balloon by use of maps and compass.

Conferences: Organization, Equipment and Training

Assignment of duties, commissioned and enlisted personnel.
Transportation and special technical vehicles.
Replacing gas lost by diffusion and expansion.
Repalcement of empty hydrogen cylinders.
Field hydrogen generators.
Field compressing outfits.
Methods of observing and indicating targets and plotting shots.
Telephone service from balloons, instruments and circuits.
Photography and sketching from balloons.
Visual signal codes from balloons.
Property damage caused by descent in free balloons.

Conferences; Balloon Construction

Kinds of fabric suitable for balloons.
Preparation and application of varnishes for cotton balloons.
Cordage for nets and suspenders.
Shapes of balloon envelopes and standard sizes.
Strip and panel construction for envelopes.
Laying out patterns for envelopes.
Various types of seams.
Designs and tests of suspension patches.
Manufacture of nets.
Types and sizes of maneouvering valves and pressure valves.
Size, location, cord attachment and replacement of rip panel.
Appendix ring, neck and cord.
Kite balloon steering bags and substitutes.
Number, size and shape of tail cups.
Strength, weight, flexibility and construction of cable for captive balloons.
Sizes, types, weight and attachment of balloon cars.
Essential features of concentrating rings.

Conferences: Gases

Kinds of gas suitable for free, captive and dirigible balloons.
Specific gravity of gases and methods of determining.
Manufacture of coal-gas and water-gas.
Production of hydrogen by electrolysis of water.
Hydorgen by steam and iron method.
Hydrogen by compression and refrigeration method.
Hydrogen by decarburation of oils.
Hydrogen by silicon-soda process.
Hydrogen from hydrogenite and hydrolythe.
Testing hydrogen for purity.
Compression of gases.
Flow of gases through pipes and orifices.
Types of gas-holders and their maintenance.

Conferences: Meteorology

Indicating and recording, barometers, thermometers, hygrometers and anemometers.
Tests, maintenance and method of mounting instruments.
Various changes in atmosphere with increasing altitude.
Movement of high and low pressure areas; direction and rate at various seasons.
Movement of atmosphere over large areas.
Local effect of vertical currents.
Cloud formations and deductions from them.
Weather maps; weather predictions, storm warnings and weather signal codes.
Tornadoes and cyclones; seasons and localities.
Average wind velocity in sections of the United States.

Conferences: Dirigible Balloons

General types of rigid, semi-rigid and non-rigid balloons, and employment of each type.
Rigid dirigibles: Dimensions, shapes and materials used.
Semi-rigid: Dimensions, shape, materials, importante structural feaures and methods of car suspension.
Non-rigid: Dimensions and shapes; maintaining shape; material for envelopes; methods of car suspension.
Air resistance to various shapes and skin resistance.
Size and arrangement of ballonets.
Employment of ballast.
Vertical and horizontal stabilizing fins.
Rudders for altitude and direction.
Number and arrangement of propellers.
Gasoline engines suitable for dirigibles.
Number and distribution and sizes of motors.
Gas engine principles and maintenance.
Dynamic reaction of atmosphere on under surface.
Velocity with respect to wind direction and earth.
Navigating instruments.
Hangars and methods of entry and exit in wind.
Designs for descending on water or land.
Bomb dropping devices—Armament.

D'ORCY'S AIRSHIP MANUAL

(Excerpts from the forthcoming "D'Orcy's Airship Manual," published by the Century Co., obtainable through the Aeronautic Library, 280 Madison Avenue)

(*Continued from page* 261)

GERMANY

Rheinisch-Westfaelische Motorluftschiff Gesellschaft, Elberfeld — Builders, to the designs of Herr Oscar Erbsloeh, of a car-girder pressure airship. Trim controlled by lifting planes and trimming tanks.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (mc)	Power (h.p.)	Speed (km)	Notes
1	**Leichlingen** (October, 1909)	53.2	10	2,900	125	50	Excursion airship.—One Benz engine; one tractor screw. Ballonet: 450 mc. Designed endurance: 6 hrs.
1a	(1910)			3,200	125	50	Was re-built and enlarged. Ballonet: 580 mc. Exploded in mid-air on July 13th, 1910, killing the crew of five including Herr Erbsloeh.

Schuette-Lanz (Luftschiffbau), Rheinau, near Mannheim—Builders of structure airships. Hull-frame of laminated wood girders, spirally wound and held under tension by wire-stays. Fabric skin. Suspended cars. Trim controlled by lifting planes.

Works No.	Name Trials	Length (m)	Beam (m)	Volume (mc)	Power (h.p.)	Speed (km)	Notes
1	**S. L. I.** (October, 1911)	131	18.4	19,500	540	71	Prussian Army airship.—11 compartments. Two Mercédès engines, mounted on two cars; each driving one pusher-screw. Best endurance: 16½ hrs. Was destroyed by a storm while moored in the open near Schneidemuehl, on July 17th, 1913.
2	**S. L. II.** (April, 1914)	144	18.4	23,000	800	87	Prussian Army airship.—Four Maybach engines, mounted on four crosswise hung cars, each driving one pusher screw. One rigidly connected pilot-car near the bow. Best endurance: 1,400 km. in 20 hrs.; altitude: 2,100 m. Performed during the early part of the Great War on the Russian front until she was, in November, 1914, badly punished by Russian gunners and appears to have subsequently been dismantled.

Schuette-Lanz (Luftschiffbau), Rheinau. (Continued)

3	**L. 4** (1914)	**165**	**18.4**	**30,000**	**1,080**	**90**	German naval airship.—Four Mercédès engines driving four pusher-screws as on *S.L.II.* Was "iron-crossed" for her co-operation in the sinking of H. M. ships *Aboukir, Cressy* and *Hogue,* on Sept. 22nd, 1914, by the submarine *U.9.* Stranded in a storm, on Feb. 17th, 1915, near Esbjerg; all of the crew saved themselves but four who perished when the airship was carried away by the storm.
4	**S. L. III.** (January, 1915)	**144**	**18.4**	**23,000**	**800**	**87**	Prussian Army airship.—*S.L.II.* type.
5	**L. 7** (February, 1915)	**165**	**18.4**	**30,000**	**1,080**	**90**	German naval airship.—Same features as *L.4.* Was shot down on May 4th, 1916, off the Schleswig coast, by H. M. ships *Galatea* and *Phaëton;* seven of her crew were made prisoners.
?	**L. 21** (1915)	**165**	**18.4**	**30,000**	**1,080**	**90**	German naval airship.—Was set on fire and destroyed with all on board on Sept. 3rd, 1916, near Cuffley, by Lieut. William L. Robinson, V.C., R.F.C.

Schwarz (David), Berlin—Builder of the first structure airships. Hull-frame of aluminum tubing; skin of 0.2 mm. aluminum sheeting. No compartments. Trim controlled by a lifting screw. No elevator, nor rudder.

Works No.	**Name** Trials	**Length** (m)	**Beam** (m)	**Volume** (mc)	**Power** (h.p.)	**Speed** (km)	**Notes**
1	**No. 1**			**5,000**	**12**		Built in Petrograd. Burst during her inflation in 1893 through the breaking of the inner wire-stays. One Daimler engine; twin-screws.
2	**No. 2** (November, 1897)	**47.5**	**14**	**3,700**	**12**	**18**	Built in Berlin.—Hull of elliptical cross-section. One Daimler engine; twin-screws and one steering screw. On her trials the airship was unable to make any headway against a wind of 7.5 m/sec. and was damaged on landing. After having been emptied the airship was completely destroyed by the wind and the vandalism of the spectators.

FOREIGN NEWS

FRANCE

Amsterdam, May 17.—The Telegraaf quotes a statement printed in a German newspaper that the noted French airman, Captain René Doumer, son of Paul Doumer, former President of the French Chamber of Deputies, who is reported missing, was shot down behind the German lines and killed.

Captain Doumer was credited in the French War Office report of March 19 with having brought down his sixth enemy machine.

Paris, May 16.—While scattering President Wilson's address to Congress inside the German lines between Laon and St. Quentin, April 13, the wings of William Dugan's aeroplane were riddled with Krupp anti-aircraft gun shrapnel from a battery 12,000 feet below. Dugan escaped unharmed, and with Edwin Parsons of Holyoke, Mass., Kenneth Marr of San Francisco distributed several thousand of the leaflets.

Paris, May 14.—This was American Day at the largest aviation school in France. Ambassador Sharp was the guest of honor during a review of the troops and an inspection of the establishment. The elaborate programme of the day culminated tonight with brilliant evolutions by a great squadron of aeroplanes.

Ambassador Sharp was accompanied by representatives of the Ministries of War, Aviation and Foreign Affairs. The Lafayette Squadron, which is composed mainly of Americans, has its home at the school and American recruits are now receiving instruction there as pilots and preparing for service at the front.

The reviewing stand was decorated with French and American flags. Soldiers cheered and filed past the stand before the Ambassador.

Later Mr. Sharp visited the quarters of the American aviators. He expressed high appreciation of the admirable facilities of the camp, which is turning out a considerable number of American pilots.

GERMANY

It might be well, some time, to forget about the practical side of aviation, and the results accomplished, and look at the romance of it all. There has recently come to hand a letter, written by a German airman, describing his last flight,—the flight in which he was mortally injured.

The letter was written by Prince Friedrich Karl of Prussia to his father, from a hospital behind the Allied lines. It follows:

"Now something about my air flight. You know I started with Walze's squadron. We cruised along the front a long time without seeing anything. We went as far north as Arras and south in the direction of Bapaume and Peronne and flew very low. On our return to the boundary we all of a sudden discovered some 900 or 1,000 meters below six or eight Vickers monoplanes. Our leader immediately went for them and I followed, not willing to leave him alone, the enemy numbering so many more machines. That our other fliers did not follow can only be explained by assuming that they did not discover the enemy in the low darkly clouds.

"How we went for them! I sometimes lost sight of the German leading machine, but always managed to find it again. Suddenly one enemy flier came my way and I attacked him. He fled. I after him. Thus I lost my only comrade.

"The enemy fliers around me increased still more in numbers. They must have noticed the dangerous condition of the men I was chasing. Meanwhile I had succeeded in manoeuvring my opponent pretty close to earth, when all of a sudden I heard the tack, tack of a machine gun behind me, and the next moment my motor stopped. The enemy behind me kept tack-tacking, with the result that soon I was wounded in the right foot. Thank Heaven, the steering levers remained intact.

"Gliding over badly battered villages and trenches, I succeeded in landing, as the Australians who captured me said afterwards, not far from the German lines. I should have liked to destroy the machine, but the enemy gunfire prevented it. My second thought was to reach our lines, but the enemy at once directed his fire at me. Still I seemed to have luck until finally a bullet pierced my spine and came out at the right of my stomach. I went down like a log.

"When finally the Australians found me, they treated me very tenderly. I had lost so much blood and was freezing with cold. Two soldiers kindly offered their great-coats and covered me with them. They carried me an endless stretch until we found a physician, but they were very careful about it."

May 19.—Destruction of the Zeppelin L-22, reported without details in an official British announcement on May 14, occurred off Esbjerg, within sight of the Danish coast, according to the accounts of eyewitnesses from villages on the shore.

These accounts indicate that not one but two Zeppelins were destroyed on that day, inasmuch as the explosion of an airship off Terschelling was reported from Holland, at a point too distant to cover the same case. The loss of the second airship is attributed to lightning.

GREAT BRITAIN

London, May 14.—British naval forces destroyed Zeppelin L-22 in the North Sea this morning, according to an official statement issued by the Admiralty. A dispatch from the east coast says news was received early this morning that the L-22 was approaching the coast. A squadron of naval aircraft went in pursuit. The Zeppelin was attacked by a battle plane which overhauled it and was seen to burst into flames.

Two members of the airship's crew jumped into the sea, *The Star* says, and the others disappeared with the burning Zeppelin.

A Zeppelin with three gondolas, enveloped in heavy smoke, was sighted today at Terschelling, Holland (an island in the North Sea), a Reuter dispatch from Harlingen, Holland, reports. When the smoke disappeared fifteen minutes later the Zeppelin was no longer to be seen.

The destruction of the L-22 marks the fourth attempt at Zeppelin raids within the last year which has ended in disaster. Two of the mammoth airships were shot down during a raid on London on September 23, 1916, and two months later two more Zeppelins were destroyed off the English coast. On March 17 French artillerymen shot down a Zeppelin behind the French lines while it was endeavoring to reach Paris.

JAPAN

The following items are taken from the *Japan Times* of March 24:

Lieutenant-General Nagaoka, retired, who is widely known as the "father of Japan's local aviation," is reported likely to announce his candidacy for the House of Representatives in the coming general election in April. If the report be true, he will contest Yamaguchi prefecture, and his candidature will in all probability be welcomed by constituents.

Miss Katherine Stinson, the American aviatress, who is now staying in Peking where she made a flight exhibition some time ago, intends to revisit this country very shortly. The lady aviator has sent the following letter to Mr. Kushibiki, who was the manager of her flight exhibition some time ago at Aoyama.

Peking, March 18.

Gentlemen—I flew here yesterday and to-day, having nice crowds. The people here have been lovely, all seemed so much interested. To-day President Li presented me with a lovely cup and I am making a night flight at his request for the people. Another cup was presented to me by the Minister of the Interior. I will be honored by the presentation of cups by the Director of Aviation, Yang Yaheng and by Shanghai. The army aviators have been helping me every day with their mechanics who have been of great assistance just as were the army and naval fliers in Japan. I can hardly wait to see my medal from the Mayor of Tokyo.

I was so sorry to hear of the accident and death of Lieutenant Sawada. I sent to the War Department a telegram and received a funeral notice. Japan has deepest sympathy in his loss.

I am impatiently looking to the day when I return to Japan when she dresses up beautifully with cherry blossoms. Best regards to the aviation press men in Japan.

Yours faithfully,
Miss Katherine Stinson.

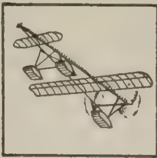
MODEL NEWS

Edited by G. A. Cavanagh



The "Paper Tube" Scale Model Airplane

Earle H. Bean

President, Harvard Aeronautical Society

The value of the paper tube scale model over the "flying stick" type as an instructor cannot be disputed. For myself, I learned as much about flying a big airplane with these models as I did my first month at one of the best flying schools in this country. While in the full sized machine it seemed as if I was flying in one of my models, suddenly grown big enough to carry me. The correct positions on getaways, spirals, and glides had been taught me already by these flying scale models, and hence it was easy to put the big machine in those very positions. The accidental position of the control wheel or the rudder bar does not matter, for the position of the machine in the air is of first and last importance.

The use of a paper tube for housing the rubber motor of a miniature flying machine is one of unrealized possibilities. Monoplanes, biplanes, triplanes and seaplanes of any tractor and of most pusher types can be built to a scale of about one inch to a foot. In actual flight the performances of these three or four ounce models is unbelievably like their big prototypes. The degree of refinement and approximation to the dimensions of the full sized aeroplanes being copied depends mostly on the skill of the model maker and very few compromises are necessary to achieve a realistic as well as a workable result. Any youngster with a previous experience in making rubber driven models of the "flying stick" type will be astonished at the success of his first paper tube model. For the grown-up who wishes to experiment with new types of flying machines here is an undeveloped field for preliminary tests. Let me explain how the simplest type of paper tube model is constructed.

The fuselage of the monoplane model here shown is made from a sheet of medium weight brown wrapping paper cut about fifteen by twenty-four inches and rolled and glued in the form of a long conical tube, and then shellaced for stiffness. After the glue had dried both ends of the tube were cut perpendicular to its axis and each reinforced with thin cardboard to prevent splitting out by the pull of the rubber motor or by blows suffered in flying.

The motor consists of six strands of one-eighth inch square rubber thread, or about six feet in all. That any model airplane, especially a scale model, should fly with so little power is remarkable. The rear end of the rubber motor is held by a "W" shaped wire hook, which slides into half-inch slots cut in the tube. The propeller end of the motor is attached to the shaft, which is bent like a fish-hook. This shaft passes through a corkstopper, which should fit in the tube so that half its length is outside and can be trimmed into a bullet-shaped nose. If the flat sided body of many standard aeroplanes is desired, it can be made of thin cardboard fitted around the circular tube fuselage. The propeller bearing consists of two brass washers. The shaft should be made of heavy bicycle spoke, looped at the front end for winding the motor with a hand drill or some other geared winder. If the rubber is lubricated with glycerine about four hundred turns can be obtained with a winder and about two hundred and fifty when cranking the propeller by hand. The best method of determining the capacity of the motor is the test to the breaking point, counting the number of turns. When winding the rubber with a mechanical winder, the motor should be pulled out to twice its normal length in order to get more turns.

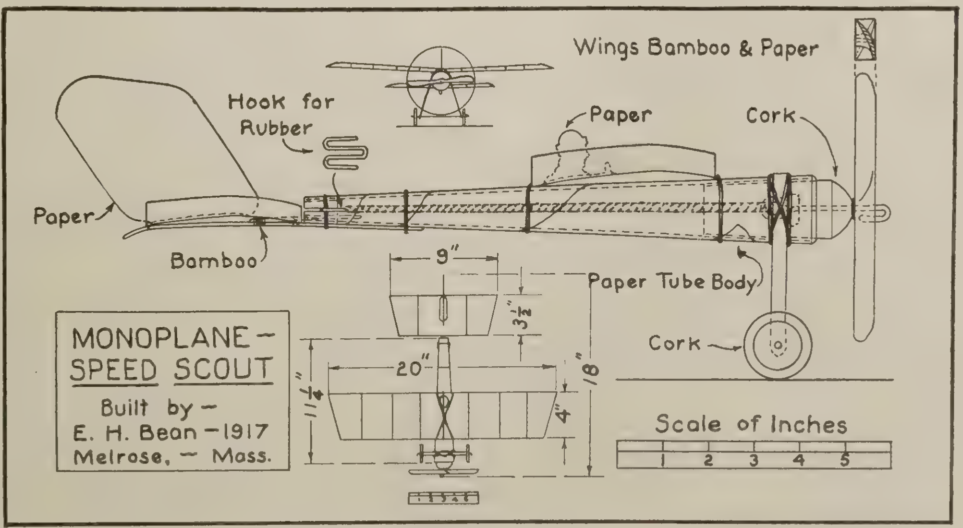
The propeller, which in this case is six inches in diameter, is of small pitch and thick blade to withstand the knocks of a tractor model. Pine propellers heavily shellaced and topped with bamboo fibre paper or china silk, will be found quite serviceable.

For the wings any light construction will do. A bamboo frame, with curved ribs and single surfaced with paper or silk, shellaced, is the easiest to make. A carefully made double-surfaced wing gives greater stability in flight. The rear wing, or elevator, is a lifting surface in this case in order that the main plane may not have to be placed disproportionally far from the propeller. A slightly less angle of incidence than that of the main plane is necessary for longitudinal balance. The rudder is made of stiff paper folded double and glued to the rear wing. Both wings have a slight dihedral. The rear wing is fastened to a strip of bamboo, which also acts as a rear skid. Another strip is tied to the first and slips inside the tube, the two pinching the tube like a clothes pin.

The landing gear is bamboo bent "U" shaped to fit the curve of the tube. A uniform curve can be made by holding the bamboo against a lighted electric light bulb, which is warm enough to bend the bamboo. Cork wheels, with brass tube hubs, and a wire axle complete the landing gear. The main plane, the bamboo strip holding the rear wing, and the landing gear are tied to the paper tube body with rubber, which allows the model to be taken apart quickly, to withstand shocks, and to be easily adjusted for balance. The complete model takes up so little room that it is advisable to glue as well as tie all but the main wing, thus making wing alignment easier.

Now let us test the model for balance. If properly adjusted it glides over a hundred feet when given a slight push from a height of six feet. After a series of test glides, wind up the motor the full amount and see that the wings are in line with each other and the axle of the landing gear.

(To be continued)



Broadway Model Aero Club

Bulletin Five V

Flying model aeroplanes is a science, to master which, requires knowledge of the fundamental laws of aerodynamics and general aeroplane construction, besides considerable practice. Two models apparently alike in every respect, say two feet long, with two propellers of the same size and the same length of rubber which when twisted supplies the motive power for the propellers, will behave quite differently when launched in the air. One may go 3,000 feet and as straight as an arrow; the other may go only a hundred feet and make a circle. The difference may be due to a number of causes, including the shape and tilt of the wings, the misplacing of the center of gravity, the pitch and size of the propellers, etc.

CASH PRIZES IN GOLD COIN will be given to the WINNERS OF EVENTS in the MODEL AEROPLANE CONTESTS to be held in Baltimore, Md.

ANY YOUNG MAN IN THE STATE OF MARYLAND IS ELIGIBLE TO COMPETE. NO ENTRANCE FEE OR CHARGE OF ANY KIND. JUST BUILD A MODEL AEROPLANE AND FLY IT. For information write to W. H. LOGUE, JR., DIRECTOR, MODEL AEROPLANE CONTESTS, 931 North Broadway, Baltimore, Md.

The Cooperation of the Aeronautic Manufactu Their Patriotic Duty and Make a Good Invest Loan Bonds on t

"Every man and woman who buys a Liberty bond will contribut conclusion. No one can doubt the outcome of the conflict if the Ameri sources of the nation."—William

To Aeronautic Manufacturers:

THE UNITED STATES GOVERNMENT $2,000,000,000 LIBERTY LOAN BONDS afford an opportunity to every man and woman to discharge their patriotic duty, and at the same time, make a good investment.

AERONAUTIC MANUFACTURERS can help their employees to do their duty and make a good investment by arranging to enable their employees to order their LIBERTY LOAN BONDS through the Company's cashier next pay day by making the first payment of two per cent of the cost of the bond and four payments thereafter.

The fact that the LIBERTY LOAN BONDS, which are authorized by Congress, are backed by the entire wealth and resources of the United States and will pay an interest of 3½ per cent per annum makes them the best and safest investment in the world today.

LIBERTY LOAN BONDS are issued in the following denominations:

Coupon Bonds: $50, $100, $500, $1,000.

Registered Bonds: $100, $500, $1,000, $5,000 $10,000, $50,000, $100,000.

The subscription books will close on June 15, 1917, and those who have failed to buy will have lost their opportunity to be patriotic and make a good investment at the same time.

The easy instalment plan arranged especially for the convenience of people of limited means enables employes of aeronautic manufacturers—no matter how small their salaries may be—to purchase LIBERTY BONDS on the instalment plan, as follows:

2% on application;
18% on June 28;
20% on July 30;
30% on August 15, 1917;
30% on August 30, 1917.

The Bonds will be delivered about July 1, 1917, or on completion of payments.

The LIBERTY BONDS are as good as **gold.** They can be sold at any time, through any bank, at the current market price, which, owing to the unusually high rate of interest for Government bonds, promises to be at a premium.

If before the termination of the war bonds are issued bearing a higher rate of interest, the holders of the bonds now to be issued may convert them into bonds bearing such higher rate, such bonds to be identical as to maturity of principal and interest and terms of redemption with these bonds, but otherwise substantially identical with the bonds of the new issue. See blank opposite page.

LOANS AND CURRENCY

LIBERTY LOAN

APPLICATION FOR BONDS

This application should be transmitted through the subscriber's bank, trust company, or other agency acting on his behalf, or it may be filed direct with the Federal Reserve Bank of his district or the Treasury Department at Washington.

Dated ....

To the Secretary of the Treasury:

According to the terms of Treasury Department Circular No. 78, dated May 14, 1917, the undersigned hereby apply for $................par value of the 15-30 Year 3½ Per Cent Gold Bonds of the United States, and agree to pay par and accrued interest for any bonds allotted on this application. The sum of $.............. is inclosed, being 2 per cent on the amount of bonds applied for (or payment in full for the one $50 or the one $100 bond applied for).

Signature of subscriber, in full..
Address—Number and street..
City or town..
County ....State ....

Note.—It is desirable that the following information be furnished by the applicant:

1. If full payment is to be made before final instalment date indicated in the circular, what will be the date of such full payment?..

2. If it is expected that future payments will be made by check, upon what bank or trust company will such checks probably be drawn?

Name of bank or trust company..
Address ....

3. What, if any, particular denominations of interim certificates are desired?........................

4. Through what, if any, bank or other agency is this application transmitted?........................

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested

The Flight of the Cuspidor

It was the good ship "Cuspidor,"
That sailed the azure blue.
Its captain was a brave bold man
To start with such a crew.

For one was deaf, and one was blind,
The rest, they could not see;
The first mate wore a pair of pumps,
Because he'd water on the knee.

The engine was a vee type eight
Of ninety-two h.p.,
(It's actual power when in flight
Was only twenty-three).

It was twelve when they turned her over,
At two they turned her back.
At three they gave the whole thing up
And went home in a hack.

For the engine wasn't working,
The ailerons were bent;
And gasoline they could not buy
Their money they had spent.

And though we may arouse your wrath;
In fact your indignation,
We must confess, the whole darn flight
Was pure imagination!

Our Own Puzzles, Conundrums and Jokes

Would you say that a famous swordsman was one with "Dual Control?" (Don't give it up—it's tricky.)

Reggie.—I see all the saloons are using Dep. Control.
Charlie.—Where do you get that stuff?
Reggie.—Well, hasn't each saloon a foot-bar?
(The verdict was "Killed in self-defense.")

Patriotic Recruiting Officer.—And when the bullets are flying right and left, the enemy is coming at us with cold steel, why, gentlemen, *why* should we be willing to give up our lives for our glorious country!

Voice from the back.—That's what I say, Captain, *why* should we?

Recruiting Officer, talking to possible recruit.—And if you are injured serving your country, we will look after you well. If you lose a finger of one hand, you get five hundred dollars; a foot lost, and you get one thousand, a leg——

Possible recruit.—That's far enough, captain. What you ought to get in the army is a lot of beetles!

War Notes

Petrograd.—Nicholas Romanoff, formerly known as Czar of all the Russias, is now busily engaged in shoveling snow. He is not willing to express an opinion on anything, for he is feeling quite put out.

Sap Center, Ky.—All the hands at the largest farm in this town are engaged in building an aeroplane, which they intend to fly, as soon as it is completed. Five new doctors have recently moved into town.

Hickville, N. C.—The Hickville Aeroplane School has been moved to Sap Center, Ky. Five prosperous M. D.'s moved with it.

Lambfry, Mo.—Gus Whoozis last week broke the world's record for altitude. His elevator got stuck and all he could do was point up.

Bulrush, Ia.—Seth Perkins, the county joker, last week pulled a good one on the boys. He said that Bulrush ought to be the home of the dirigibles, because there was more hot air passed around in Bulrush than in any other town in the county. "Pretty good, Seth," say we.

A Head Start

Captain.—Now boys, fight like the devil, and when your ammunition gives out run for your lives. As I am a little lame I'll start now.

A Long Search

A good story is told of an Irish Regiment, now at the front in Europe. It seems that one day one of the Irish soldiers came back with a splendid pair of Turkish boots on his feet. His friend Pat approached him.

"Say Mike," says Pat, "where did you git thim boots?"

"Took them away from a Turkish officer," says Mike.

The next day Pat disappeared. As each day passed his friend gave up hope of ever seeing him again, and at last had him posted as missing. However, one day, two weeks later Pat came staggering into camp with a splendid pair of Turkish boots on his feet; boots which far outshone the boots Mike was wearing. Pat came up to Mike, took the boots off and handed them to him.

"Mike," he said, "look at them boots. I got them at last, but I had to kill nineteen Turks to get a pair to fit me!"

Technical Queries Answered

K. L. A.—Aeroplane wings *stagger* when they are overloaded.

P. O. S.—Sorry, but we can buy no inventions this week.

U. A. X.—Your former position as a flagman on a railroad would not fit you for a commission in the Signal Corps of the Army.

L. A. W.—You are the eighth correspondent this week who has invented a machine for doing away with submarines.

O. R. D.—Your box of cigars very gratefully received. By all means write us again.

W. D. B.—So you flew from Philadelphia to Brooklyn? But why pick out such places?

By George! I do believe there's a boat going to come through this canal!

employ as many aviators as are available from the Army, Navy, U. S. Army Aerial Reserve Corps, Naval Reserve Flying Corps, Aviation Sections of the Militia of different States, and instructors connected with civilian aviation schools, not only to create public interest in the Liberty Loan, but also to give experience to the military aviators in cross-country flying, and give a demonstration of the efficiency of the present Army and Navy aeronautic organizations.

The aviators attached to the military and civilian—or only the Army and Navy—stations will fly to other points within a radius of between 200 and 300 miles to different points of the compass, so as to practically touch simultaneously all the important geographical points by aeroplane, carrying educational pamphlets and circulars urging the public to buy Liberty Loan bonds.

For instance, two or more aviators from Governor's Island and Mineola can fly to Philadelphia; two or more to Troy and Albany; two or more to Buffalo. The aviators from Essington, Pa., can fly to Harrisburg, Pittsburgh, and other points. The aviators from Newport News can fly to Baltimore, Richmond, Raleigh, N. C., Lexington, Ky., and other important Southern points. The aviators from Buffalo, N. Y., can fly to Erie, Pa., Cleveland, Akron, Detroit and Toledo. The aviators from Boston can go to Portland, Me., and any cities in New Hampshire and Vermont. Aviators from Detroit can fly to Dayton, Cincinnati, Indianapolis, South Bend and Grand Rapids. The aviators from Chicago can fly to St. Louis, Springfield, Ill., Davenport and Des Moines, Ia., and Minneapolis. The aviators from Memphis can fly to Nashville, Tenn., Birmingham, Ala., Jackson, Miss., and Little Rock, Ark. Aviators from Fort Omaha can fly to Kansas City, St. Joseph and to important cities in Kansas, Nebraska, South Dakota and Minnesota. The aviators from San Antonio, Tex., and Columbus, N. M., can fly to cities in those States. The aviators from San Diego can fly to important cities in California, Arizona and Nevada. The naval aviators from Pensacola, Miami, West Palm Beach and Newport News can fly to the various cities along the coast.

If the plan of the Aviation Section of the U. S. Signal Corps to establish additional aviation stations throughout the country are far enough developed, it may be possible to have aviators cover the entire Lincoln Airway during one or more days, the aviators from different points flying to other points about 300 miles apart.

Whenever possible, the aviators, besides carrying educational pamphlets regarding the Liberty Loan bonds may carry members of the Liberty Loan Committee, who will on landing be received by the city authorities, and will deliver addresses urging the public to buy Liberty Loan bonds.

To add interest to the Aerial Rally, the Aero Club will present each aviator who reaches his destination a $100 Liberty Loan bond, and it is estimated that it may be possible to have as many as 100 aviators participating in the rally. If the rally only lasts one or two days, it will not take the aviators from their pressing duties, but will afford them experience in quick aerial mobilization, in cross-country flying, and give a demonstration of our increasing aerial preparedness. It will show that in the event of its being necessary to protect railroads, bridges, or important bases, the Army and Navy aviators could quickly be sent to the point to be protected.

The public interest that will be created in the Liberty Loan bonds by such a rally will be tremendous. There always has been great interest in aerial preparedness, and the fact that a portion of the funds to be raised by the Liberty Loan bonds is to be spent in the upbuilding of our aerial defenses will create additional public interest.

The decision as to the carrying out this plan rests with Brig.-Gen. George O. Squier, Howard E. Coffin, the Chairman of the Aircraft Production Board, and the Navy authorities.

EVERYTHING IN RUBBER FOR AIRPLANES

BALLOONS OF ANY SIZE AND EVERY TYPE

Extending Vision on Land and Sea

The far-ranging dirigible and the swift airplane overshadow for many the important function of the kite balloon.

But the perfecting of power-propelled aerial scouts has merely defined that function more clearly.

The kite balloon is necessary because it is a stable and readily available aid in determining ranges, in observing the effects of fire, in extending vision on land and sea.

Before the new Goodyear type was tested and approved the problems demanding better solutions were the primary ones of material and stability.

The former our work for many years on balloons of any size and every type has solved.

The latter demanded newly directed labor in design and ungrudging research in the field, in our own country and abroad.

The result of the Goodyear effort is the new Goodyear kite balloon—80 feet long and of 25,000 cu. ft. capacity.

Even as years of achievement have justified the Goodyear fabrics, exacting tests have justified the finned and reinforced tail cups and the design of every part.

GOODYEAR
AKRON

A Lewis used as an anti-aircraft gun masked in wheat field
Official photograph (Crown copyright) taken on the front in France

"MODERN Warfare has developed a real necessity for machine guns both light and heavy, but as far as I saw, the Lewis Gun far outnumbered all other machine guns of the light type among the Allied armies.

"In the last engagement I saw in the recent Somme offensive, whole detachments were going into the trenches with every man carrying a Lewis Gun as one would carry an ordinary rifle."

SAVAGE ARMS COMPANY

Executive Offices: 50 CHURCH STREET, NEW YORK
Plant: 1671 SAVAGE AVENUE, UTICA, NEW YORK

THREE MEDALS OF MERIT were awarded by the Aero Club of America for the following notable records:

J. FLOYD SMITH, who created three new World hydro altitude records in a Martin seaplane: January 12, 1916, with one passenger, 12,333 feet; January 11, 1916, two passengers, 9,524 feet; February 16, three passengers, 9,608 feet.

C. C. CULVER, Captain, U. S. A., for his great achievements in developing wireless equipment for sending and receiving messages from aeroplanes. All his experiments and achievements were made using a Martin Military Tractor Biplane.

A. D. SMITH, Corporal, U. S. A., who created a new hydro duration record February 19, 1916, in a Martin seaplane by remaining in the air 8 hours and 42 minutes.

Many other performances of note prove the certainty and efficiency of our designing and the superior construction of our aircraft.

WRIGHT-MARTIN AIRCRAFT CORPORATION
60 Broadway -:- New York

Pigeons As Messengers

Mr. Frank J. Griffin has offered to supply the Aero Club of America with carrier pigeons to be used as a means of communication between aeroplanes and home stations to be established by the various Aerial Coast Patrol Units which have recently been formed.

Mr. Griffin in his letter says:

"It will be conceded without argument that a vital necessity exists for a method of communication between the aviator and his base station, not only to report important events coming under his observation but also injuries or difficulties to him or to his machine, in order that aid may be furnished at the earliest possible moment.

"Wireless is not available on our present flying machines for sending messages; homing pigeons are practicable, and are available for use in aeroplanes should they be required.

"In this connection, I might state that I have had the honor of being instrumental in some degree of the taking up of the pigeon service by the Signal Corps of the U. S. Army, and am at the present time assisting in the installation of lofts at various Government coast forts, and in particular at Governors Island and at Mineola Aviation Station, at which points the birds are to be used in connection with the aviation section of the Signal Corps.

"For your information, a homing pigeon will always return to the place from which it is first flown, and therefore, in the establishment of new lofts, we use young birds (squeelers as they are called), which are five to six weeks of age, and have never flown, giving them their first flight from the new loft; after a few months they are capable of flights of from 200 to 300 miles, and with reasonable care and attention are then practically 90 per cent. certain.

"These young birds are quite valuable, a bird of good stock being worth anywhere from $5.00 up each, but, as a matter of patriotism and to insure to the benefit of the fighting arms of our country, myself and various of my pigeon fancier friends are giving the birds to the Government at a nominal price of five cents a bird, to comply with the army regulations.

"The Signal Corps of the Army is now constructing a model loft, which, when completed, and approved as to details of construction, will be duplicated at various other points selected. Such a loft capable of housing 100 birds can be constructed and equipped for less than $100 per loft, and delivery of the birds to it could be had almost as soon as the loft is constructed.

"I feel safe in stating that if the Aerial Coast Patrol, the Naval Reserve Aviation Section and the Naval Militia Aviation Section wish to avail themselves of the use of homing pigeons I can secure for them as many birds as they require and free of all expense that is not absolutely necessary to comply with army or naval regulations."

Radio Operators in Military Aeronautics

Skilled wireless operators for the Mosquito Fleet are being recruited from the ranks of the amateurs, among whom there are many operators of the highest grade of skill and technical knowledge.

The Aeronautic Reserve will require a large quota of radio men and it is only from this field, the amateur wireless telegraphers, that they can be enrolled.

The practical skill of the amateur and his remarkable ability to secure the utmost distance with the limited power he was permitted to use by law, has caused him to establish distance records for a given power that have not been approached by naval and commercial stations. A large number of stations before the declaration of hostilities regularly communicated eight hundred and a thousand miles, and occasionally much longer distances.

The record established for transmitting, using one kilowatt of power, is three thousand miles overland—from New York to Los Angeles.

Radio telegraphy from aeroplanes is a recent art, and its widespread use in military aviation finds us wholly without trained reserves. The large number of young men who have taken up radio work from a pleasure standpoint are only partly trained, but obviously a partly trained man is more valuable than an untrained one.

The knowledge which he possesses is essential, but there remain many things which he must acquire to be a real military aviation telegrapher. The mere ability to tap a key in a room of his own home may make the amateur wireless operator believe that he can perform the same service while breezing along in a machine in flight, but it requires but one aeroplane flight to convince him that the continuous vibration of an aeroplane in flight is not as comfortable or as easy a place in which to operate.

His physical and nervous system must first be trained to maintain its full control over his hand and brain so that he can operate his aeroplane radio set with the ease that he can operate a land station.

The aspiring radio man must perform the function of observer as well as wireless operator. In the British training system, all military pilots are taught the elements of the art of radio telegraphy. While we are probably going to follow the British curriculum in the training of our own airmen, the lack of facilities for training pilots and the immediate need for all we can procure may find us using radio operators who have been trained as observers, without being pilots. In fact, such a course would cut in half the training time of each man, since the acquirement of even a working knowledge of radio telegraphy takes many weeks of conscientious work.

Hence men who possess knowledge and experience in radio telegraphy may be used as passenger observers and operators. The training of an observer, however, is no small task. It includes a thorough study of military terminology and theory, so that only facts of importance and value are reported. The spotting of artillery fire also requires study and practice in the judging of distances.

With the expanded use of aeronautic radio for military purposes, the duties of operators become doubly important. Increased range and efficiency of aeroplane transmitters now makes it possible to report observations during long distance scouting trips; and there have been cases reported of attacks of infantry being directed by officers in aeroplanes—their orders being sent to the troops below by radio.

To supply this need of men in aeroplane radio operators, we have a large field of young men to draw from. The amateur licenses held by American citizens number more than ten thousand. To hold a Government license these men have passed an examination both in theory and code, and in practise become very skilled operators. Before the war, 65 per cent of the operators of the Marconi Service were recruited from amateur operators.

With numerous records of skill and efficiency in the radio art, and in many cases possessing the physical qualifications necessary for aeroplane work, the wireless amateur who has some knowledge or interest in aeronautics forms a desirable and advanced recruit in military aviation. The need for men in the Naval Reserve Flying Corps of such qualifications is an important one, and information regarding terms of enlistment can be secured at 26 Cortland Street, New York City.

ALWAYS KEEP THE CHART IN SIGHT

Aeronautic Maps

THE Aeronautic Library has secured the exclusive agency from the Sperry Gyroscope Company for the sale of the Sperry Aeronautic Maps and is now ready to deliver maps New York-Chicago; New York-Newport News; Long Island and vicinity, etc.

Every aviator appreciates the value of an accurate map when making cross-country flights, and the Sperry Aeronautic Maps, and Sperry Map Holder, supply this necessity.

The map can be turned easily in the holder bringing constantly before the aviator a chart of the locality above which he is flying.

The equipment is light in weight and can be fixed to instrument board without interference with the other instruments.

Prices and details on application.

The Buck Automatic Aerial Torpedo

After a series of exhaustive tests in Colorado, the Buck Air Craft & Munition Co., who own and control the Buck Automatic Aerial Torpedo Patents, are prepared to negotiate with Governments and other parties for production on a quantity basis.

The Buck Automatic Aerial Torpedo is an air craft equipped with a 50 H.P. Motor, and designed to carry explosives through the air to any distance up to thirty miles. A time controlled release drops the torpedo at any given distance.

The entire equipment is automatic and is launched from a compressed air catapult mounted on a motor truck, the engine of which furnishes the air for the catapult.

The torpedo can be fired at any range and at any degree of the compass.

The launching of the torpedo is without shock, and consequently the most dynamically explosive materials can be carried.

All-Metal Aeroplanes

This company is developing a series of all-metal aeroplanes which can be manufactured lighter than the ordinary aeroplane and at the same time insuring greater durability. Patents are applied for on a special wing construction which is designed to eliminate all tendency to side-slip when the machine is in the air.

The Buck Gravity Stabilizer will be used on all machines manufactured by the company.

Burgess Primary Training Tractor Type B. P.

This machine was designed by W. Starling Burgess at the request of the United States Army for a primary training tractor aeroplane having a practical side by side seating arrangement with duplicating controls.

This has been accomplished without sacrificing in the least the efficiency or appearance of the machine.

It fills the urgent need found at present in the aviation schools—giving great range of control and allowing the instructor to be at side of the pupil during flight, thereby facilitating instruction.

This has proven very satisfactory in experimental flights as well as in the official trials thru which this machine passed with great success.

TRAINING TRACTORS
for
IMMEDIATE DELIVERY

Government Officials authorize sale to private parties to relieve congestion at training camps

So as to encourage and increase aviation training, Government officials have authorized the sale to private parties of Standard Model J Primary Training machines, built for the Government to full specifications, and passed by Government inspectors. The J has a high factor of safety, and is equipped with a special safety landing gear, which prevents nosing over. It has a low landing speed of 37 m.p.h. Several of these machines that have passed Government inspection are now complete and ready for immediate delivery. A large number of these are being built for the Government use, thus assuring quick deliveries of spare parts. It is expected by the War Department that the opening of the sale of the machines to private parties will relieve the congestion of men at the training camps, due to lack of machines. Further information on request.

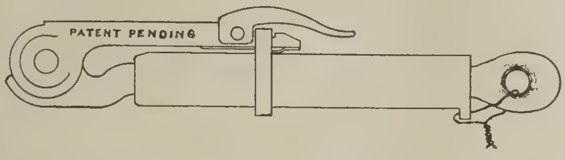
The Bellanca Turnbuckle

A Labor and Time Saving Invention

The purpose of this turnbuckle is to pull together and tighten or loosen, as may be desired, a metallic cord or cable. This is obtained by turning the sleeve in one direction or the other to suit the required purpose.



The advantage of this turnbuckle over all other types is that it can be attached and detached without changing the screw adjustment of the turnbuckle. It can easily be attached or detached, at the same time eliminating the necessity of readjustment.

The *Bellanca Turnbuckle* is manufactured to meet the recognized requirements of strength, weight and durability.

From the description above given, the advantages of the *Bellanca Turnbuckle* over all other types will readily be seen and appreciated.

PRICES ON APPLICATION

All price quotations withdrawn. There has been a rise of ten to twenty-five dollars per thousand feet on all classes of this lumber during the last thirty days, and the probabilities are that the grade 3 inches thick and thicker, 6 inches wide and wider, ten per cent; 10 to 17 feet long, ninety per cent; 18 to 40 feet, seventy-five per cent vertical grain, **four sides clear** straight grain, not less than ten annular rings to the inch, will be $200.00 per thousand f. o. b. New York within sixty days. Many foreign buyers are on the Pacific Coast and are taking all offerings. It is advisable to place contracts at once for a season's supply before the price rises further or the grade is exhausted. No aeroplane spruce older than 4 to 6 months is available and spruce should be air dried nine months and longer to achieve the best results. In purchasing, care should be taken to buy from a specialist the grade known as **four sides clear, free from all knots and sap pockets.** Some aeroplane builders not conversant with these specifications have made purchases which were practically valueless for construction work.

PERFORMANCE

The New York Aero Construction Company's Twin Motored Seaplane has a maximum speed of 85 miles per hour, excelling the estimate by ten miles per hour. Yet it has a slow landing speed of 43 miles per hour, allowing the landings to be made within a much smaller space than is ordinarily the case. But what is even more important in coast defense work is the fact that it has a

FLYING RADIUS OF NINE HOURS

The advantages of a high speed and a wide flying range are obvious. The coasts of the United States are long, and the swifter the machines that guard them, and the longer they can stay in the air, so much better and more easily are the coasts patrolled. The seaplane mentioned in the editorial of the World could, flying at full speed for its seven hours' flying radius, cover 515 miles. The seaplane of the New York Aero Construction Company could cover 680 miles.

820 Sq. Ft. Supporting Surface.
Two 100 H.P. Aeromarine Motors.
Weight 2,700 lbs. Useful load 1,700 lbs.
Maximum speed, 85 Miles per hour.
Minimum speed, 43 Miles per hour.
Flying radius, nine hours.

Designed and constructed throughout under the supervision of Mr. Warren S. Eaton.

FIRE-PROOF YOUR AEROPLANE

REMARKABLE NEW AEROPLANE DOPE AND REAL FIRE-PROOF PAINT

that meet every standard requirement, and in addition

INSURE FIRE PROTECTION

This remarkable new Dope, besides being absolutely fire-proof, will by our process render your plane fabrics

Drum Tight and Strong, Absolutely Smooth, Water and Weather-Proof and is Non-Poisonous in Application, Tough and Flexible, with Proper Shrinkage Allowance, and our

REAL FIRE-PROOF PAINT

WILL ABSOLUTELY PROTECT YOUR WOODWORK AGAINST FIRE

Oil and gasoline spilled or splashed on plane surfaces, if ignited by engine backfire, cannot burn fabrics treated with our new dope—the fire cannot touch the fabric and will not spread beyond the oil covered area.

SPAR VARNISH REMOVER

We also make a "cleaner" or spar varnish remover with which spar varnish can be easily and quickly removed without in any way affecting the under coating of our special fire-proof dope. It makes the re-doping of any part or the whole of a surface a simple and easy matter and eliminates the necessity of disassembling and reconstructing the part affected, with a saving and economy that can be readily appreciated.

"IT'S IN

THE SPOKES"

THREE MEDALS OF MERIT were awarded by the Aero Club of America for the following notable records:

J. FLOYD SMITH, who created three new World hydro altitude records in a Martin seaplane: January 12, 1916, with one passenger, 12,333 feet; January 11, 1916, two passengers, 9,524 feet; February 16, three passengers, 9,608 feet.

C. C. CULVER, Captain, U. S. A., for his great achievements in developing wireless equipment for sending and receiving messages from aeroplanes. All his experiments and achievements were made using a Martin Military Tractor Biplane.

A. D. SMITH, Corporal, U. S. A., who created a new hydro duration record February 19, 1916, in a Martin seaplane by remaining in the air 8 hours and 42 minutes.

Many other performances of note prove the certainty and efficiency of our designing and the superior construction of our aircraft.

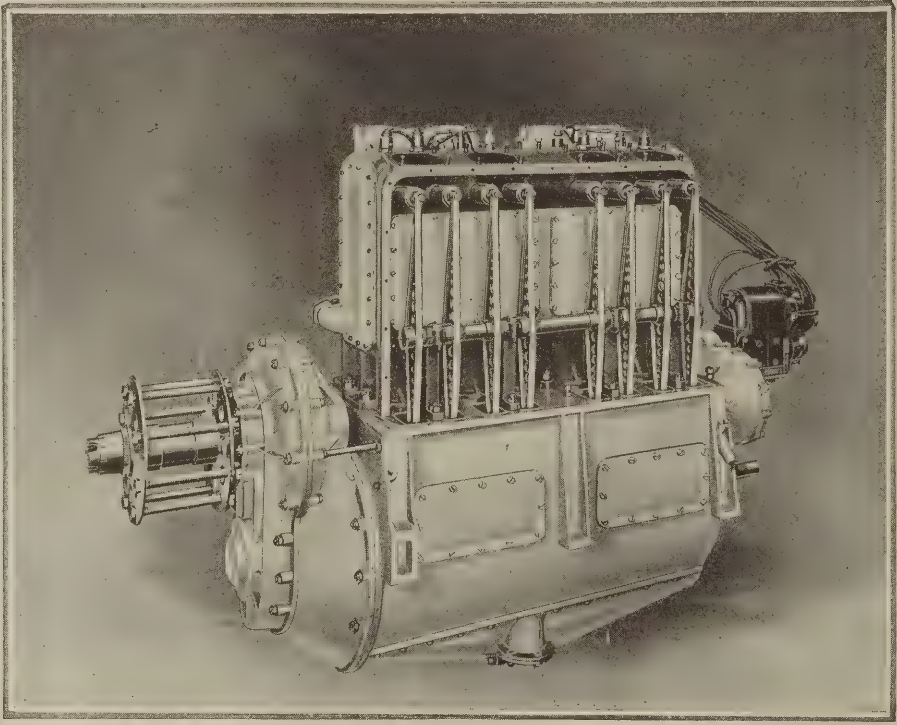

ILLUSTRATION WITH VALVE COVER REMOVED TO SHOW VALVE ACTION

Brief Specifications

Sixteen Valve Duesenberg Aeroplane Motor

FOUR cylinder 4¾" x 7", 125 H.P. at 2100 R.P.M. of the crankshaft and 1210 R.P.M. of the propeller. Motors are sold on above rating; actual power tests prove this motor capable of developing 140 H. P. at 2100 R. P. M. of the motor. The exact weight with magneto, carburetor, gear reduction and propeller hub, as illustrated, 509 lbs. Without gear reduction, 436 lbs. Net price of this four cylinder motor with regular engine equipment but not with reduction gear, $3050.00; net price with reduction gear, $3500.00.

Cylinders are semi-steel with aluminum plates enclosing water jackets. Pistons specially ribbed and made of Magnalite aluminum compound. Piston rings of special Duesenberg design, being three piece rings. Valves are Tungsten Steel, $1\frac{15}{16}$" inlets and 2" exhausts, two of each to each cylinder. Arranged horizontally in the head, allowing very thorough water-jacketing. Inlet valves in cages. Exhaust valves, seating directly in the cylinder head, are removable through the inlet valve holes. Valve stems lubricated by splash in the valve action covers. Valve rocker arms forged with cap screw and nut at upper end to adjust clearance. Entirely enclosed by aluminum housing as is entire valve mechanism. Connecting rods are tubular, chrome nickel steel, light and strong. Crankshaft is one piece forging, hollow bored, 2½" diameter at main bearings. Connecting rod bearings 2¼" diameter, 3" long. Front main bearing 3½" long; intermediate main bearing 3½" long, rear main bearing 4" long. Crankcase of aluminum, barrel type, oil pan on bottom removable. Hand hole plates on both sides. Strongly webbed.

Full and complete information will be cheerfully supplied and every courtesy extended to you in carrying out your investigations. Our factory facilities are such that satisfactory deliveries can be made.

VOL. V NEW YORK, JUNE 4, 1917 No. 12

TO TRAIN THOUSANDS OF AVIATORS AND PRODUCE TENS OF THOUSANDS OF AEROPLANES TO STRIKE GERMANY THROUGH THE AIR

"We Must Strike Germany Through the Air" is the new slogan which has resulted from the meeting in Washington between members of the Aircraft Production Board of the United States and the Board of Governors of the Aero Club of America, after lengthy study of the present war situation and of the ways and means of carrying on an effective campaign of education on behalf of the Allies.

Mr. Alan R. Hawley, the president of the Aero Club of America, who returned yesterday from Washington, issued the following statement:

"Germany's U-boat warfare and the necessity of keeping the German fleet bottled up are occupying the navies of the Allies, and no decisive victory over the Germans is expected in naval actions in the near future. Likewise advances against the Germans on land are slow and Germany has seemed able so far to always throw new thousands of men and new lines of trenches and countless guns to meet the advance of the Allies. The only victories on the part of the Allies so far have been as a result of supremacy of the air, as a result of the matching of skillful, daring Allied aviators against German aviators and observation balloons; the recent British and Italian victories were preceded by countless aerial fights in which hundreds of aviators took part, and it was not until the skies had been cleared of German aviators and of German observation balloons—and the Germans were thereby deprived of the aerial eyes of the infantry, of the aerial scouts and the Allies aviators, being masters of the air, could follow the movements of the enemy and locate their batteries and their strongholds—that the victories became possible.

"These facts are known to the men who, although pressed by the countless details of preparing this country to do in a few months what should have been done in the past years—still are able to look upon the situation from the broadest aspect and to see in which direction lies the possibility of accomplishing the utmost against Germany in the least period of time. While the United States is beginning to help substantially now, effective help of the kind that leads to permanent victory can only come at the end of months of preparation, and in considering in which way we can best prepare to help to achieve permanent victories it is found that the aerial branch of the service affords the greatest possibilities. British, French, Russian, Italian and American authorities who have studied the matter closely have come to the conclusion that the addition of 10,000 aviators to-day to the Allies' present aerial forces would insure blinding the German batteries and preventing German aviators from conducting operations over or near the Allies' lines. An additional 10,000 aviators would make it possible to conduct aerial raids on a large scale and to strike Germany in the most vital places, to strike hard enough to lead to permanent victories."

Authorities in Perfect Agreement on Issue

The authorities who met in Washington, although they had all thought separately and had all made plans separately from information secured from independent sources, readily agreed in that one thing—that every effort should be concentrated in striking Germany through the air.

Several instances during the meeting emphasized that although different people present had secured their information from separate sources, their information was practically alike. For instance, when one of the authorities present stated that he would read a certain communication from Europe giving a résumé of the situation, Mr. Henry A. Wise Wood, the chairman of the Conference Committee on National Preparedness, asked permission to retire to another room until the communication had been read, because, as he stated, he had prepared an address to deliver the following day on the situation from information secured from independent sources, and did not want to place those present and himself in the embarrassing position that might follow if the information was similar, so he stepped out of the meeting room until the communication was read. When he returned and he stated the nature of the information that he had and which he would include in an address there was found that it was exactly like the information contained in the communication which was read at the meeting.

The meeting of the Board of Governors of the Aero Club of America was held in Washington and Mr. Howard E. Coffin, the chairman of the Aircraft Production Board, who is also a member of the Board of Governors of the Aero Club of America, presided. The members of the Board of Governors of the Aero Club present were: Alan R. Hawley, president of the club, and Messrs. James A. Blair, Jr., W. Redmond Cross, Charles Jerome Edwards, Max H. Fleischmann, John Hays Hammond, Jr., Captain James E. Miller, Raymond B. Price, Henry A. Wise Wood and Henry Woodhouse.

Having reached the conclusion that efforts must be concentrated to get and train thousands of aviators and lay plans to manufacture tens of thousands of aeroplanes of different types for training, bomb-dropping, artillery spotting, fighting machines and submarine destroyers, the Board next turned to consider the way and means of getting the aviators and machines.

Facilities to be Greatly Extended

To do this the aviation training facilities and the sources of supplies for aircraft must be greatly extended. It was pointed out that at the beginning of the war Great Britain did not have one-third of the aeronautic manufacturing facilities that we have in the United States to-day and there was read a statement from the British Comptroller of Aeronautic Supplies reporting that there are 958 firms engaged on work for the British Directorate of Aeronautic Supplies, 301 of which are direct contractors and 657 are sub-contractors. This report states that the total number of hands employed by the fifty firms of most prominence is 66,700.

Great Britain Spending $575,000,000 for Aeronautics

There was also brought out the fact that the present British budget for aeronautics for the present year totals $575,000,000. These are made public as a result of their publication in connection with a discussion which took place in the House of Commons recently. England and France had to come up from a production of a few aeroplanes per month to the present production of about 4,000 aeroplanes per month and have had to do that with limited resources in personnel and materials. The United States to-day has a better start than either France or England had at the beginning of the war, and it has tremendous resources in workmen and materials.

It is all a question of making a plan extensive enough to insure large production and of placing orders for continuous deliveries of aeroplanes and training of aviators and mechanics in large numbers. To do that there will be required large appropriations but no trouble is anticipated in that direction. The members of the Board of Governors of the club who discussed the matter with members of Congress were the same men who last year went to Congress to urge the increase of the appropriations for aeronautics from $3,000,000 to $30,000,000. Congress allowed $18,000,000 last year and the members of Congress seen by Governors of the Aero Club state that they appreciated that the increasing of the appropriations last year gave us a year's start in the manufacturing of aeronautic products. Now they appreciate the necessity of looking ahead again and providing for adequate expansion. For obvious reasons, the details of the plans for expansion cannot be made public. But sufficient is made public to assure the American public that proper attention is being given to meeting this need for large numbers of aeroplanes and aviators.

General Squier's Plans for Training

The Government's Committee on Public Information has issued the following statement regarding part of the details of the steps already taken to train aviators in large numbers:

"Last month a group of Army officers visited the training camp of the Royal Flying Corps at Borden, Ontario, one of the four camps established in Canada, and the aviation school at Toronto, where cadets are trained under military discipline for the service. In these schools there has been incorporated the latest European experience in the development of this new art of the air.

"Our officers were deeply impressed with their observations and as a result we called together here the heads of six prominent engineering schools which also have military training and made plans to establish a similar system in the United States. The six institutions are the Universities of California, Texas, Illinois and Ohio, Massachusetts Institute of Technology and Cornell University. Three technical instructors from each of these places were sent to Toronto. They returned on May 8 after a comprehensive study of the course given there, prepared to teach it themslvs. On May 10 these six engineering schools opened similar cadet aviation schools at their respective institutions.

"These cadet schools might be described as laboratory courses in aviation. The students are given thorough instruction in the theory of flying, including the necessary physics and mathematics and the mechanics of aeroplane construction. The training schools are thoroughly equipped with samples of aeroplane parts and instruments for demonstration as well as text-books. Technical matters relating to map making, photography, bomb-dropping, gun sighting and all similar subjects which a military aviator must know are also taught. All during this time the cadet is under military training, following the methods which Great Britain and Canada have found so successful. At the end of two months of this preliminary work, the cadet is given a final test to determine whether he shall go on to the aviation camp.

"General Squier's office has been handling these schools. All applications from persons who wish to become military aviators have been turned over to this department over which Professor Hiram Bingham, of Yale, has been given general direction by General Squier, and there have been far more applicants than could be admitted. The schools began on May 10; twenty-five cadets a week are entering each of the six colleges, which means that as soon as the first entering class completes its preliminary work, approximately 150 students a week will be available for the regular training camp with a good ground work on which to start their practical training. There will be 600 cadets in the six colleges by July 1st. In the meantime plans are going ahead from the nine aviation fields to receive their men when they are ready. The Aircraft Production Board is working constantly with the military departments in preparing for the construction of these fields. The standard field on which we are basing our program will provide for accommodating two squadrons of 150 students each with the necessary officer, instructors and enlisted men, together with a certain number of additional enlisted men who will be trained at the same time. The hangars will take care of seventy-two planes. The preparation of these fields will cost approximately a million dollars each, including the construction of the necessary buildings, dormitories, work shops and hangars. A standard set of buildings has already been worked out, the fields will be approximately a mile square, and great care is being taken by the military officers in their location.

"We are estimating about four months as the period for getting these students ready for Army service.

"The Aircraft Production Board is working hard to assist the military departments in their plans to have all these related activities co-ordinated—to have the preliminary schools turn out their cadets in order to fit into the plans for the training camps, and at the same time to get the necessary training machines ready in time for their use. These new plans will not interfere in any way with the present use of the four aviation fields the Government now has nor with private initiative.

Aircraft Manufacturers' Association Co-operating

"Both the manufacturing problem and the training problem will be much simplified the second year if we can establish the proper co-ordination of effort this year. The manufacturing capacity can easily be doubled the second year. In securing the co-operation of the manufacturers in placing their facilities at the disposal of the Government, we have found the organization of the Aircraft Manufacturers' Association, effected last February, of great assistance.

"A prominent British general has asserted that America's greatest contribution to the war will be aircraft and aviators. We believe that once started upon quantity production American mechanical genius will overcome any present obstacles to the progress of the art.

"The Aircraft Production Board is acting in the closest cooperation with the War and Navy Departments, especially with the recently created Joint Army and Navy Board on Design and Specifications, which has been entrusted by the two Secretaries with discretion on all questions of design and specifications in all forms of military aircraft except Zeppelins. The membership of this Joint Board includes the following: Major B. D. Foulois, U. S. A.; Captain V. E. Clark, U. S. A.; Lieut. A. K. Atkins, U. S. N.; Lieut. Comm. J. H. Towers, U. S. N.; Asst. Naval Constructor J. C. Hunsaker, U. S. N.; Captain E. S. Gorrell, U. S. A.; Henry Souther, the consulting engineer of the Signal Corps will act in a similar technical capacity to the Aircraft Board.

"The general function of the Aircraft Production Board is to bring manufacturers together and help make their resources available to the Government and assist the Government in stimulating the production of better types and greater quantities of air machines, to investigate and recommend manufacturing plants where orders are to be placed, to aid in arranging with American factories as to the kind of machines best suited to their several organizations and facilities for manufacture, to advise as regards priority of deliveries of aircraft material in accordance with a general policy as determined by the Council of National Defense, and following the selection of sites for Aviation Schools and supply depots by the Military Department, to advise in regard to buying or leasing the land, preparing it for use and erecting all buildings."

Aero Club of America Greatly Pleased Over Plans—Offers Hearty Co-operation

The members of the Board of Governors of the Club who attended the meeting agreed not to add to the information given out by the Committee on Public Information but they—including the aeronautic experts who have in the past few years been urging aerial preparedness on a large scale, and are usually considered very critical in their views—expressed themselves as being fully satisfied with the general plans of action. The Board of Governors of the Club, as a whole, assured the Aircraft Production Board of the hearty cooperation of the Aero Club of America and its affiliated aero clubs and pledged their co-operation in every way possible for carrying out the plans. Chairman Coffin of the Aircraft Production Board, asked the Board of Governors to continue their work in assisting in recruiting aviators and mechanics, stating that although thousands of applications have been received, such a large number of men are needed to make aviators and mechanics, that it is desirable to have as many applications as possible in the Chief Signal Office of the Army.

The members of the Aircraft Production Board besides Chairman Coffin are Brig. Gen. George O. Squier, Chief Signal Officer, U. S. A.; Rear Admiral D. W. Taylor, Chief of the Bureau of Construction, U. S. N.; S. D. Waldon, former Vice President of the Packard Motor Car Company; E. A. Deeds, former General Manager of the National Cash Register Company, after with the Dayton Engineering Laboratory Company, and head of the Miami Conservation District formed to guard against a repetition of the Dayton flood, and R. L. Montgomery, senior member of the Philadelphia firm of Montgomery, Clothier and Taylor, who is serving as financial and business advisor of the Board.

THE NEWS OF THE WEEK

College Balloon School

Washington.—The Collegiate Balloon School, to train men in the operation of lighter than air machines—the first to be established in the United States—is to be located at New Haven, Conn., under authority of the War Department, where the facilities and equipment of the Connecticut Aircraft Company will be utilized. New England universities and colleges are expected to supply the majority of the students, who will be admitted to the school through the department and who will be obliged to conform to the requirements of the military regulations.

General Squier has communicated with Colonel Isaac M. Ullman, president of the New Haven Chamber of Commerce, expressing the interest of the department in the enterprise and declaring a readiness to make an agreement for the training of army flyers at New Haven. It is expected that within a short time 200 men will be stationed at New Haven to be instructed in the art of operating dirigibles, spherical balloons and kite observation balloons. Students from Yale, Harvard, Amherst, Trinity and other educational institutions have interested themselves in this branch of aeronautics and will make up the bulk of the student body of the school. Plans are now being perfected for starting the training course at an early date.

Italian High Commission Arrives

Headed by the Prince of Udine, who is also a captain in the Italian Navy, the Italian War Commission reached Washington on May 23. The members were met at Union Station by Secretary of State Lansing, Counsellor Polk and the Italian Ambassador, Count di Cellere. They were escorted from the station to the home of Joseph Leiter in Dupont Circle, which had been placed at their disposal during their stay. Two troops of Cavalry preceded the automobiles. Other members of the commission accompanying him were: Marquis Luigi Borsarelli di Rifreddo, Under-Secretary of State for Foreign Affairs; Guglielmo Marconi, inventor of the wireless; Senator Augusto Ciufelli, formerly Minister of Public Works; Francesco Severio Nitti, formerly Minister of Agriculture; Cavalliere di Parente, Secretary of Legations and Missions; Naval Lieut. de Seara; Cavalliere Alviz Bragadin and Cavalliere Guido Pardo, secretaries; the Duca di Sangro, Signor di Sousa, Cavalliere Angeli and Cavalliere d'Amato. Accompanied by members of the mission and by his American aids, Lieut. Col. John C. Gilmore, Jr., U.S.A., and Lieut. Comdr. William N. Jeffers, U.S.N., the Prince of Udine and other members of the mission called on the Secretary of State on the following day and later on Secretary of the Navy Daniels. From the office of Secretary Daniels the members of the mission went to the White House to pay their respects to the President. In the evening the commission were guests at a dinner at the White House.

Insignia for U. S. Aircraft

The Secretary of the Navy on May 21 issued a general order providing for the adoption for Navy aircraft of a white star with a red center on a circular background of blue as the distinguishing insignia of the third arm. This insignia, which will be carried also by the Army aeroplanes, is described as follows: "A five-pointed white star inside of a blue circumscribed field, with the center of the star red. The diameter of the circumscribed circle will be equal to the chord of the wing on which the insignia is placed. The diameter of the inner circle will not extend to the inner points of the star by an amount equal to one twenty-fourth of the diameter of the circumscribed circle. The inner circle will be painted red; that portion of the star not covered by the inner circle will be painted white and that portion of the circumscribed circle not covered by either inner circle or star will be painted blue. The shades of red, white and blue will be the same as those used in the American Flag."

The order in regard to naval craft continued: "One of each of these insignia will be placed on the upper surface of each upper wing, and one of each in a corresponding position on the lower surface of each lower wing. Both sides of that portion of the rudder which is in rear of the rudder post will be painted with three equally wide bands, parallel to the vertical axis of the aeroplane and colored red, white and blue of the same shades as mentioned hereinbefore, the blue band being nearest the rudder post, the white band in the center, and the red band at the tail of the rudder.

"One of these insignia will be placed on top and one on bottom of gas bag of dirigible balloon, the center of each insignia being in the vertical plane through the fore and aft axis of the gas bag. The center of insignia on top will be sixty feet from forward end and the center of insignia on bottom will be just forward of suspension band. The circumscribing circle of insignia for dirigible will be five feet in diameter. The rudder of each dirigible will be marked in a manner similar to that applied to aeroplanes, except that stripes will not exceed five feet in length or eighteen inches in width. If there is more than one rudder only the outboard side of each outboard rudder will be marked. One of these insignia will be placed on top and bottom of gas bag of captive balloon, the center of each insignia being in the vertical plane through the fore and aft axis of the bag, and two and one-half feet aft of the seam joining nose to main body. The circumscribing circle will be five feet in diameter. The building number of each aircraft will be placed in figures three inches high on each side of the rudder, at the top of the white band hereinbefore mentioned. No other markings shall be placed on any Navy aircraft, except such as may hereafter be prescribed. All Navy aircraft will be immediately marked in accordance with this order, and in future, specifications for Navy aircraft will require that the contractors place the building number and distinguishing insignia on all aircraft, and on such spare parts as bear these marks in completed aircraft."

Frithiof G. Ericson, Chief Engineer of the Canadian Aeroplane, Limited, who was recently appointed a member of the Ministry of Munitions in Canada.

Arrangements Made for Aviation School

Columbus, O.—Professor William T. Magruder of the department of mechanical engineering, Professor Henry C. Lord of the department of astronomy, and Professor William A. Knight of the department of industrial arts of Ohio State University, have returned to Columbus from Toronto, Canada, where arrangements were completed for the work of the aviation camp which is to be established on the campus of the university. The camp, which may be started by June 1, will accommodate 200 students. The course will take eight weeks for completion, after which the students will go to Dayton for actual flying lessons.

In order to take the course, enlistment must be made in the aviation division of the signal corps of the regular army. The regular blank received at any local recruiting station must be filled out and sent with three letters from reputable citizens to Washington to the chief signal officer of the United States Army, and the regular physical examination must be passed. If accepted, the applications are to be sent to the nearest cadet aviation school for three weeks of intensive drill.

$325,000 Sought for Air Stations

Washington, D. C., May 24.—An appropriation of $325,000 for acquiring coastal air stations at Cape May and other points was requested of Congress today in a communication from Josephus Daniels, Secretary of the Navy, to Champ Clark, Speaker of the House.

"The navy has adopted in its plans for the establishment of coastal air stations at various points along the coasts," Mr. Daniels said. "Thorough investigation of sites on the Atlantic, Pacific and at Pearl Harbor have been made by boards appointed for this purpose and reports submitted. Every effort has been made to locate these stations on government land, but there remain certain sites which can only be leased or purchased. In view of the fact that some of these stations should be permanently acquired by the navy, it is strongly recommended that such sites be purchased."

Aviation School for Oklahoma

Tulsa, Okla.—Under arrangements perfected between the Chamber of Commerce and G. L. Bumbaugh, an aviator and aeroplane manufacturer, there will be located here within the next few weeks an aviation school and factory for the manufacture of aeroplanes to be used privately and in the government service.

Captain Bumbaugh was present at the noonday luncheon of the board of directors of the Chamber of Commerce and presented a brief outline of his plans, which were accepted as entirely feasible. In connection with the school, although under separate business management, the captain will conduct an aeroplane manufacturing plant which has been financed by local capitalists.

Minnesota Aero Club Organizing

Fifty prospective aviators already are waiting for completion of the plans for the Minnesota Aero Club that they may start training.

The club is being organized at the request of the Aero Club of America, who asked Mr. R. M. Newport to start a campaign for members.

Mr. Newport, with the assistance of J. A. O. Preus, state auditor, received word from fifty men who wish instruction and he said that the club will have a membership of more than 200 within a few months.

Admiral Peary is to speak in St. Paul June 20 at a meeting of the Minnesota State Bankers' Association, and if the Aero Club is fully organized at that time, will address the airmen.

Mr. Newport said, should enough members enlist, the government will probably furnish a commissioned instructor and aeroplanes.

Miss Marie Peary Soon to Be Bride

Rear Admiral and Mrs. Robert E. Peary announce the engagement of their daughter, Miss Marie Anighito Peary, to Edward Stafford, son of Justice Wendell P. Stafford, of the Supreme Court of the District of Columbia.

No date has been set for the marriage of Miss Peary and Mr. Stafford, as he has applied for a commission in the Officers' Reserve Corps.

Mr. Stafford is a graduate of Dartmouth. Miss Peary was born farthest north of any white child, her mother having accompanied Admiral Peary on one of his trips to the Arctic, and is widely known as the "Snow Baby." She is singularly unaffected and charming, and has many warm friends in Washington, where she has lived most of her life. She is a member of the Junior League, has been active in philanthropic work, and is keenly interested in aviation. She learned to fly under the tutelage of her father, who is a governor of the Aerial Club of America, and a member of the Aerial Coast Patrol.

Expert Mechanics Needed

The Aero Club of America has received a call for mechanics, expert in gas explosion engines, who are willing to enlist in the Aviation Division of the United States Army for foreign service. The men wanted for this purpose must be experts in gas engines.

Their pay will be from $36 a month to $75, with twenty per cent additional for foreign service, with all clothing, food and expenses of transportation additional. Applicants should apply to the Aero Club of America, No. 297 Madison Avenue.

There will also be opportunity for young men of good character desiring to enlist as privates and be attached to this organization. This is one of the most important branches of the service, and will afford valuable experience to suitable applicants, and the discharge from the service as aviation mechanicians after the period of the war will be invaluable in the aviation industry.

School for Eastern Illinois

Danville, Ill.—The government is planning to establish an aviation field and school in Eastern Illinois some time in the near future. A committee is visiting a number of locations and has just completed a tour of Champaign, where a site near St. Joseph strongly appealed to the members. The government is said to be considering the buying or leasing of a tract of land of 640 acres, and it is said a force of 1,500 men would be put to work immediately. The Danville Chamber of Commerce has taken up the matter with Congressmen Joseph Cannon in an effort to land the enterprise for Danville. It is pointed out to the congressman that the old car shops at Tilton would make a desirable shop for the manufacture of the machines and for their repair, while the new fair grounds would be well adapted for the aviation school. Also the tract of land owned by the government just north of the Soldiers' Home, would be available for the school. The aviation meet was held a few years ago at the latter place.

Danville has everything in the way of healthful surroundings and railroad facilities and would be an ideal place for the aviation home of the middle west. It is stated that a second commission will shortly visit this section of the country in an effort to decide upon a definite location.

Many Use Princeton as Center

Princeton, N. J.—Princeton may become the aviation training center of the East, with every resource of the university devoted to making our fighters.

Two hundred and fifty-eight enrolled students of flying now practicing on four planes under three instructors headed by James S. Barnes, former war correspondent and aviator, are anticipating that the Government will commandeer the Princeton flying school. If so, all airmen in the district between northern New York and Texas may be trained there.

Existing Government bases, at Esington and in other localities, are to be used for training mechanics and the auxiliary supply men, according to Mr. Barnes, who addressed the Princeton Club at 1223 Spruce Street. The actual flyers will be chosen from college men.

Every Princeton student is to be given a chance in learn aviation free, to maintain allied aeroplane supremacy. Graduates here are collecting funds to continue the work until Government inspection of the Princeton equipment is complete.

New School for Memphis?

Memphis, Tenn.—An enthusiastic meeting at the Chamber of Commerce marked the auspicious beginning of a campaign to bring a larger and permanent aviation school to Memphis. The campaign was given impetus by Senator McKellar's suggestion from Washington that Memphis had a splendid chance.

Memphis has become greatly attached to the aviators.

When it became known that the temporary school at the Driving Park, had been recalled to Ashburn Field in Illinois, a meeting was called at the Chamber of Commerce, to take the matter up with the proper officials.

Mayor Ashcroft was sent for. He attended the meeting.

Senator McKellar telegraphed that was pretty certain that a permanent school could be secured for Memphis if the city or the Chamber of Commerce could guarantee a tract of at least 640 acres of land with a half dozen or so landing places within 50 miles of Memphis. The Chamber of Commerce quickly replied that it could guarantee this.

Later Mayor Ashcroft received another telegram from the senator saying that the guarantee made it reasonably certain that Memphis would get an aviation school.

Meanwhile the Chamber of Commerce appointed a committee, composed of R. L. Jordan, W. E. Gage and C. W. Butler, to take charge of the campaign.

Personal Pars

"Beating his father to it," was the expression used by Cecil H. Braddick, of the Conway-Bogue Realty Company, when he left Denver for San Diego, where he will join the United States aviation corps. Young Braddick is the son of A. B. Braddick, of the library bureau. Cecil had said nothing to his father about offering his services to the government, and when the elder Braddick arrived one evening and saw a packed suitcase standing near the door, he wondered who was going to elope.

Cecil said his father had been bragging so much about going to Fort Riley while his three sons had been doing nothing but tend to business that he had decided he would be an aviator.

Dr. W. J. Humphreys, Professor of Meteorological Physics, U. S. Weather Bureau, addressed the Cornell Chapter of Sigma Xi on Thursday, May 17, in Rockefeller A. The subject of his talk was "The Atmosphere and Aviation." The lecture was illustrated.

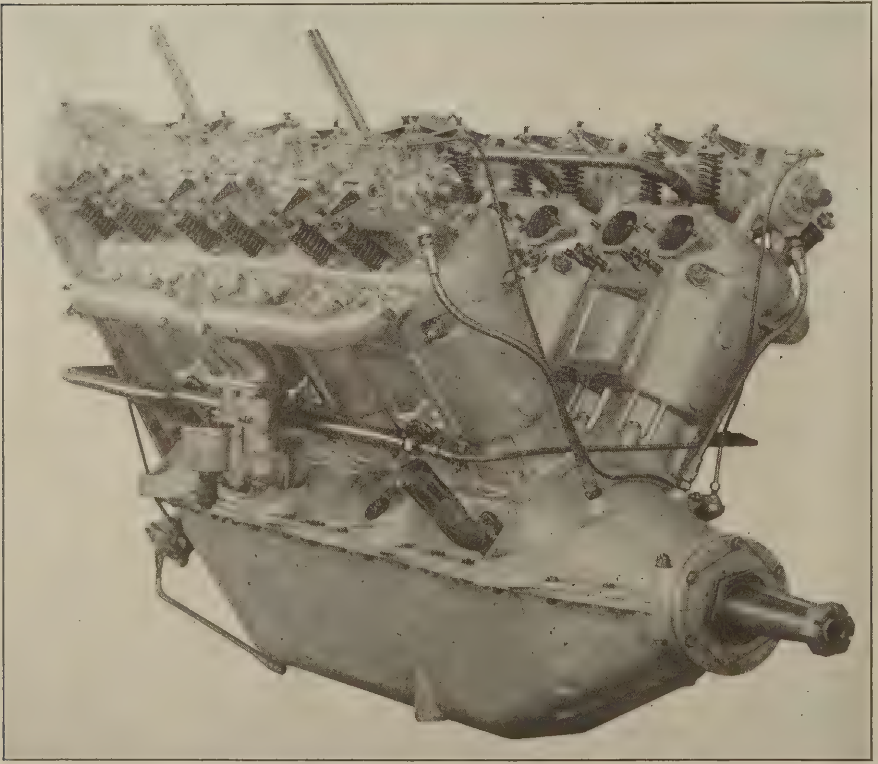
De Lloyd Thompson, the well known aviator, will soon give a series of exhibition flights in Wheeling, West Va. Although Mr. Thompson has not fully recovered from his accident sustained last fall, it is said that he is able to fly with all his old ability.

Aviation Training Near Dayton

Dayton, Ohio, May 21.—The United States Government has leased 2500 acres of farm land north of this city for an aviation training school. It will be a four-squadron school, the largest in the world. The Wright aeroplane school, organization of which was recently announced in AERIAL AGE, will assist in giving flying lessons.

To Develop Aeroplane Mechanics

Detroit, May 24.—The Government has asked all automobile factories for the names of their most expert mechanics. About 100 will be sent to France to gain experience in aeroplane construction and later will return to develop this work here.



The Wisconsin Twelve. Described on page 388 of this issue.

Northampton Aero Club Organized

Bethlehem, Pa.—The Northampton County Aero Club has been permanently organized with these members: Charles T. Hess and Harold T. Magee, Bethlehem; Howard Riegel, Henry McKeen, Henry Chidsey, George R. Elder, Sr., C. Norvin Rinck, H. W. Zook, W. Evan Chipman, R. B. Bridge, Charles M. Laubach, T. A. H. Hay, George M. Shook and R. K. Broadwee, Easton; F. B. Franks, Bath; Willis A. Flory and Thomas J. Kichline, Bangor; Dr. Howard Ott, Portland; John A. Miller and William H. Milchsach, of Nazareth. George M. Shook was elected secretary and Charles T. Hess treasurer. T. A. H. Hay is the president.

Technology Man Has Wireless Invention

Marlboro.—Dr. O. H. Stevens of this city declares that his son, Louis W. Stevens, a graduate of the Massachusetts Institute of Technology, has invented devices which, when attached to wireless telephone instruments, will make it possible for aviators to communicate with each other or with persons on the ground while they are high in the air.

He gave but few details concerning the devices. The most difficult problem to solve in the instruments that would make it possible for aviators to talk with each other, he said, was to overcome the noise made by the whirring of the aeroplane propellers and the "chugging" of the motors.

Personal Paragraphs

Roy F. Mitchell and H. J. Wells will train the members of the Kansas City Minute Men's Aero Squadron. A Curtiss military tractor will be used.

John N. Willys, of the Willys-Overland Co., was recently appointed a director in the Curtiss Aeroplane & Motor Co.

Anti-Aircraft Force to Protect New York City

To provide adequate protection against possible attacks of Zeppelins or enemy aeroplanes on New York the Veteran Corps of Artillery, its strength increased from forty-six members to seven hundred within two months, is drilling regularly and receiving instruction similar to that given the anti-aircraft fighters of Paris and London soon after the war began.

The corps is endeavoring to raise by its own efforts a sum of $100,000, which will be expended in the purchase of mobile batteries of rapid fire guns. Batteries will be stationed in Manhattan, Brooklyn, Queens and Richmond.

The Veteran Corps of Artillery was organized in 1790, and for many years has occupied an unusual position in the State militia, membership being accorded to those veterans who had achieved merit. While the corps is not upon the same military standing as the National Guard, its efforts to protect New York City against air raids will be official. In fact, when the National Guard is called from the city the Veteran Corps may represent the largest unit intact in the city and its services may therefore be used in other ways than as anti-aircraft fighters.

Following the informal announcement by the corps that it would be used for anti-aircraft fighting a membership campaign was begun and the corps of forty-six members two months ago now numbers seven hundred.

Among the members of the corps have been many who were commissioned officers of high rank in the army and navy as well as in the National Guard of various States. Major General Frederick D. Grant was a member until his death, and his son is now a member.

Naval Camp Officially Opened

Boston.—The naval aero station at Squantum was opened May 11, when the property was turned over to the United States Government by Acting Adjutant General E. Leroy Sweetser, representing Governor McCall. Captain William R. Rush, commandant of the First Naval District, received the camp in behalf of the Navy Department. "Colors" were run up while the marine band played.

Captain Rush then issued orders for the conduct of the camp in compliance with orders received from Washington to assume control of the camp, which is officially designated as "Naval Air Station, Squantum, Mass."

Lieutenant E. W. Spencer, Jr., U. S. N., has been detached from the Pensacola Aero Station and ordered to report for duty at the camp, and will be in charge. Lieutenant Spencer has not yet arrived and meantime Lieutenant Edward G. Blakeslee, U. S. N., will be in charge.

Twenty students will be given instruction at the camp and twelve mechanics will be on duty there. Assistant Paymaster Turner is the supply and commissary officer of the camp and he will have two civilian ensigns as assistants, G. Richard Fearing, Jr., and R. D. Thomas, both of the Reserve Corps.

INSURANCE FOR AVIATORS

The National Advisory Committee for Aeronautics has endeavored to interest a number of life and accident insurance companies in the subject of insurance for aviators. At first, only the more prominent companies were approached on the matter. The committee will endeavor to interest all the companies in the United States as far as practicable, and if favorable responses are received, a further bulletin will be issued on this subject.

The following is a digest of the propositions that have so far been submitted to the committee by such companies as have already expressed a willingness to insure aviators:

Aetna Life Insurance Company. Issues a war permit covering military service in the United States without charge, and beyond the United States for a charge of $50 per thousand. This includes incidental aviation but company does not care to insure men who are to make a business of aviation and who are not in the military service of the United States. Company desires to place as little restriction upon enlistment and army service as practicable, and consequently, for the present, is carrying the risk of aviation along with army service. Limit of amount which will be written upon army officers and men is $5,000 on commissioned officers, $3,000 on non-commissioned officers, and $2,000 on enlisted men.

Home Life Insurance Company. Will accept mechanics and others engaged in the manufacture of aeroplanes and allied work at standard rates. Considering the question of insuring aviators.

John Hancock Mutual Life Insurance Company. This company has agreed to certain recommendations made by a joint conference of a selected committee of the Insurance Commissioners of the several States and of the officers of the insurance companies, in regard to war conditions. The extra annual premium for the war hazard has been set for the present at $37.50 per $1,000 of insurance. This is a uniform rate and applies to service here as well as abroad or to flying over the water. The company reserves the right to charge an additional premium or to increase the present one whenever circumstances seem to call for such action. This company will accept army aviators for $1,000, and those in the aviation service who are prohibited from serving as aviators or from flying in any capacity, whether as testers, demonstrators or instructors, for the sum of $2,000 to and including ratable age 25. At ages 26 to 35 inclusive, the company will accept on those in the service, other than on those who fly, the sum of $5,000 maximum, provided they are single men with dependents, or are married men. To such as are single without dependents the limit is $2,000. The company will, of course, require suitable evidence that a person in the aviation service is not eligible to serve as a flier, either as pilot, passenger or in any other way, before it can issue more than $1,000.

Mutual Life Insurance Company of New York. "Regarding men who are employed in connection with aviation, but do not go into the air in flying machines, we do or we do not insure such men, according to the circumstances of each case. In some cases, we may think that there is a fair chance of the man in question becoming an aviator, and in such a case we would not issue a policy. If we considered that there wer no chance of his becoming an aviator, then we would probably issue him insurance."

National Life Insurance Company. Men who are employed in connection with aviation, but who do not go into the air, considered on Ordinary policies.

New York Life Insurance Company. Aeronauts, aviators, and men engaged in the manufacture of aeronautic devices, who occasionally fly, provided they do not give exhibitions and do not undertake trick flying, will be considered for a maximum amount of $2,000 with an annual extra premium of $25 per thousand, together with a war clause. The extra premium will be eliminated from the policy one year after they have given up flying either as an occupation or as a pastime, subject to evidence of insurability satisfactory to the company. A refund will be made of the extra premium paid during that year.

The war clause provides for a single extra premium of $100 a thousand in event of engaging within two years from the date of issue in any Military, Naval, Red Cross or other relief service outside the boundaries of continental United States. (The boundaries of continental United States are defined to include the waters within three miles of the coast line, but do not include the Panama Canal Zone.) If the insured does not pay the extra premium, and dies within the first two years from date of issue of the policy as the result, directly or indirectly, of engaging in the service already mentioned, the insurance is limited to one-fifth of the face of the policy.

The foregoing provisions would not apply to persons who are in the service of, or who volunteer for service with, a foreign power.

This company does not issue to persons in hazardous occupations the so-called disability benefits or double indemnity benefits.

The Northwestern Mutual Life Insurance Company. "This company does not insure aviators or persons known to contemplate aviation or likely to engage therein. We do not, however, as to our war service regulations, make any distinction by way of discriminating against those persons who, having entered military or naval service, are attached to the Signal Service branch and engage in aviation." Policies issued prior to April 10, 1917, are entirely free of restriction, but in the case of policies issued subsequently, there is a military or naval service provision, the conditions of which are avoidable only upon payment of such extra premium as the company may require. The extra rate has been fixed temporarily at $50 per thousand, and the same flat rate holds regardless of the branch of service or place of service."

The Prudential Insurance Company of America. "We are prepared to consider applications for insurance from aeronauts on the basis of what is known in this company as 'Hazardous Ratings.'

"This would mean an extra premium rate on Whole Life policies varying from about $8 at the youngest ages to $13 at age of 40; on Twenty-Payment Life policies an extra premium of about $10 at the youngest ages and about $13 at age 40; and on Twenty-Year Endowments an extra premium of between $4 and $5 at the youngest ages and about $8 at age 40.

"As an illustration of the gross premium including the extra, the Whole Life rate at age 25 would be $25.58 per $1,000 of insurance; the Twenty-Payment Life rate, $34.42; and the Twenty-Year Endowment rate, $46.50.

"Such policies would be limited in amount to $2,000 and would contain the company's regular war clause, which provides for an extra premium of $100 a thousand for service in the Navy, and an extra premium of $100 a thousand for service in the Army outside of the United States as constituted before the year 1898. The extra premium on account of occupation would be included as a part of the $100 extra premium; in other words, the gross premium would never exceed the company's standard premium rate plus the extra premium on account of war. No extra premium would be charged for military service within the United States."

"Will not insure aviators not actually in or who do not intend to be in the Government service.

The Travelers' Insurance Company. Will insure aviators attached to the Army or Navy on the same terms as members of any expeditionary force sent abroad. Will not issue accident insurance, but will issue life insurance on the Ordinary or higher premium life forms with an additional premium of 10 per cent of the amount of insurance per annum. The amount of insurance is limited to $1,000 an individual.

Union Central Life Insurance Company. Policy holders subsequently employed as aviators or in connection with aviation will be placed upon the same basis as those entering the Army and Navy.

Accident Insurance for Aviators

No definite proposition has yet been submitted to the committee on the subject of accident insurance for aviators.

The North American Accident Insurance Company is making an investigation of the subject and will take the matter up with other accident insurance companies, with the idea of establishing a uniform policy.

The New Amsterdam Casualty Company is endeavoring to bring about the formation of a pool of accident insurance companies, and is willing to take its pro-rata share of the business.

ARMY AND NAVY NEWS

Applications are being received from thousands who wish to join the Reserve Flying Corps, more than 800 names being registered in Boston alone. The applicants include college men, motor salesmen, mechanics, chauffeurs and men who are interested in racing cars and speedboats. The number of names sent in has enabled the officers in charge to secure a picked lot of men for the first quota, most of which already is in training. Several new training camps are being established and the men will be sent as rapidly as accommodations are assured.

Brig. Gen. George O. Squier, C.S.O., U.S.A., has written a letter to Frank H. Bethell, vice-president of the New York Telephone Company, of New York City, in which General Squier says that telephone employees can best serve the Government by remaining at their posts and continuing to give efficient service. "In the conduct of the war that is upon us," writes General Squier, "the service furnished by your company and by all telephone companies will be of the greatest importance. You will be called upon to meet demands of the most urgent kind. You have been called upon, and you may be called upon further, to furnish men trained in the art of constructing and maintaining telegraph and telephone lines."

The Aero Squadron Aviation School and the aviation field, located south of San Antonio, are detached from Fort Sam Houston and made an independent command, according to a memorandum issued from Southern Department headquarters at Fort Sam Houston. The new command is designated Aviation Camp, San Antonio, and it has been directed that all mail, etc., be sent there, as it will henceforth be considered a unit separated from the local Army post.

Major William Mitchell, Aviation Section, examination, original vacancy, to be Lieutenant Colonel with rank from May 15, 1917.

Major Charles S. Wallace, examination, vice Mitchell, detail in Aviation Section continued, to be Lieutenant Colonel with rank from May 15, 1917.

Captain Arthur S. Cowan, original vacancy, to be Major with rank from May 15, 1917.

First Lieut. Carlyle H. Wash, 6th Cav., to Fort Bliss, Tex., for examination of physical qualification for detail in Aviation Section, S.C.

Private Arthur E. Brown, Signal Corps, Fort Slocum, N. Y., will be sent to Mineola, Long Island, N. Y., for duty at the Signal Corps Aviation School.

Capt. Joseph C. Morrow, Jr., junior military aviator, Signal Corps, is designated as aeronautical officer of the Central Department.

Lawrence Leon's class at one of the aviation training grounds.
